Angular values of nonautonomous and random linear dynamical systems

Wolf-Jürgen Beyn∗  Gary Froyland †  Thorsten Hüls∗

Abstract. In this contribution we introduce the notion of angular values for nonautonomous linear difference equations and random linear cocycles. We measure the principal angles between successive subspaces of fixed dimension under the nonautonomous or random linear dynamics. An ergodic average is formed and two types of angular values result for each dimension, either by first taking the supremum over all initial subspaces and then letting time tend to infinity or by reversing these processes. The relations between the various types of angular values are analyzed and their existence is proven for random dynamical systems. We treat the autonomous case in detail and show how angular values can be obtained from generalized eigenspaces. This leads to a numerical algorithm for computing angular values via Schur decompositions and one-dimensional optimization. For one-dimensional subspaces in two-dimensional systems our approach agrees with the classical theory of rotation numbers for orientation-preserving circle homeomorphisms if the matrix has positive determinant and does not rotate vectors by more than \( \pi/2 \). Because our notion of angular values ignores orientation by looking at subspaces rather than vectors, our results apply to dynamical systems of any dimension and to subspaces of arbitrary dimension.

Key words. Nonautonomous dynamical systems, random dynamical systems, angular value, ergodic average, principal angles of subspaces, numerical approximation.

1. Introduction. In this paper we propose and analyze suitable notions of angular values for linear nonautonomous discrete time dynamical systems. The systems are of the form

\[
 u_{n+1} = A_n u_n, \quad u_0 \in \mathbb{R}^d, \quad n \in \mathbb{N}_0
\]

with \( A_n \in \text{GL}(\mathbb{R}^d) \), i.e. with real invertible \( d \times d \) matrices \( A_n, n \in \mathbb{N}_0 \). Our goal is to study the average rotation of \( s \)-dimensional subspaces \( V_0 \subseteq \mathbb{R}^d \) for \( s = 1, \ldots, d \) when iterated as in (1.1), i.e. we consider the sequence of subspaces generated by

\[
 V_{n+1} = A_n V_n, \quad n \in \mathbb{N}_0,
\]

so that \( V_{n+1} = V_{n+1}(V_0) \) depends on \( V_0 \) via \( V_{n+1} = A_n A_{n-1} \cdots A_1 A_0 V_0 \). Since the matrices \( A_n \) are invertible the subspaces \( V_n \) have the same dimension \( s \) for all \( n \in \mathbb{N}_0 \). Their rotation is measured by the well-established notion of principal angles between subspaces which originates with C. Jordan in 1876. By \( \angle(V, W) \) we denote the maximum principal angle of two subspaces \( V, W \) and we recall that \( 0 \leq \angle(V, W) \leq \frac{\pi}{2} \) holds. Some basics of the theory of principal angles and of their numerical computation may be found in [18], [12, Ch.6.4]. Generalizations to complex vector spaces and the triangle inequality appear in the papers [10], [16], [29]. In Section 2 we derive some specific results, tailored to our needs, such as estimates of principal angles in terms of norms and an angle bound for linear maps. Using
principal angles between the spaces \( V_j(V_0) \) generated by (1.2) we form the \( n \)-step average

\[
\frac{1}{n} a_{1,n}(V_0), \quad \text{where} \quad a_{1,n}(V_0) = \sum_{j=1}^{n} \angle(V_{j-1}, V_j), \quad n \geq 1
\]

and two types of limiting values

\[
\bar{\theta}_s = \limsup_{n \to \infty} \sup_{V_0 \in G(s,d)} \frac{1}{n} a_{1,n}(V_0), \quad \hat{\theta}_s = \sup_{V_0 \in G(s,d)} \limsup_{n \to \infty} \frac{1}{n} a_{1,n}(V_0),
\]

where \( G(s,d) \) denotes the Grassmann manifold of \( s \)-dimensional subspaces of \( \mathbb{R}^d \). We call \( \bar{\theta}_s \) the \( s \)-inner and \( \hat{\theta}_s \) the \( s \)-outer angular value of the system (1.1). In sections 3-4 we will discuss systems for which the limsup s in (1.4) are actually limits. More variations of these notions will be defined in Section 3.1, and some key examples will be presented in Section 3.2 which show that all types of angular values differ in general.

Perhaps the simplest example is a \( 2 \times 2 \) orthogonal matrix, where \( d = 2, s = 1 \) and

\[
A_n \equiv A = T_\varphi = \begin{pmatrix} \cos \varphi & -\sin \varphi \\ \sin \varphi & \cos \varphi \end{pmatrix}, \quad 0 \leq \varphi \leq \frac{\pi}{2}.
\]

All summands in (1.3) are \( \varphi \) and \( a_{1,n}(V_0) = n \varphi \) for all one-dimensional \( V_0 \subset \mathbb{R}^2 \). Hence we find \( \bar{\theta}_1 = \hat{\theta}_1 = \varphi \) in this case.

A first motivating example is the following randomized version. Let \( (\Omega, \mathbb{P}) \) be a probability space, \( \tau : \Omega \to \Omega \) be an ergodic transformation preserving \( \mathbb{P} \) and \( \varphi : \Omega \to [0, \frac{\pi}{2}] \) be a random variable. Setting \( A(\omega) = T_{\varphi(\omega)} \) and \( A_n = A(\tau^n \omega_0) \) for some \( \omega_0 \in \Omega \) we see that \( a_{1,n}(V_0) = \sum_{j=0}^{n-1} \varphi(\tau^j \omega_0) \) for every \( V_0 \). By Birkhoff’s ergodic theorem, for \( \mathbb{P} \)-almost every \( \omega_0 \), one has \( \lim_{n \to \infty} \frac{1}{n} a_{1,n}(V_0) = \int \varphi(\omega) \, d\mathbb{P}(\omega) \). The above general formula holds for driving systems \( \tau \) modelling any stationary deterministic or stochastic process. In Section 4 we generalize the various notions of angular values to the general setting of random dynamical systems (cf. [1]). We establish their existence via ergodic theorems and prove inequalities between the various types; see Theorem 4.2.

A second motivating example is to abandon orthogonality and change (1.5) by a skewing factor \( 0 < \rho \leq 1 \) to

\[
A_n \equiv A(\rho, \varphi) = \begin{pmatrix} \cos(\varphi) & -\rho^{-1}\sin(\varphi) \\ \rho \sin(\varphi) & \cos(\varphi) \end{pmatrix}, \quad 0 < \varphi < \pi.
\]

This matrix turns out to be a kind of normal form with regard to measuring angles between a one-dimensional subspace and its image (see Proposition 5.2). The angular values \( \bar{\theta}_1 \) and \( \hat{\theta}_1 \) agree in this case, but they differ from \( \varphi \) in general and depend critically on the value of \( \rho \) (see Proposition 5.2 and Theorem 6.1).

As a physical motivation of angular values consider an object, such as a stick or a sheet, carried along by a fluid flow, for which one wants to measure its maximum average rotation. In mathematical terms we think of a continuous time dynamical system \( \dot{u} = F(u) \) determining the trajectory of the object, and we assume that the system (1.1) describes its linearization about the trajectory when sampled at discrete time instances. Then the first and second angular value measure the maximum average angle of rotation exerted by the flow on a line \( (s = 1) \) or on a plane \( (s = 2) \). In view of such an application it
is natural to extend the quantities (1.4) to continuous time systems, but this has not yet been pursued.

There is a weak analogy of first angular values to Lyapunov exponents which measure the maximum average exponential growth of a linear nonautonomous system (1.1); see e.g. [1, Ch.3.2], [5], [17, Suppl.2]). For the latter purpose it is enough to compare the norm of the last iterate with the first one and average the logarithm. However, in the angular direction one expects only linear growth, and periodicity requires to add up the angles of every single step and then average.

For certain systems, the above definition of angular values is related to existing concepts of measuring rotations in dynamical systems, which we now discuss.

Let us first mention the classical theory of rotation numbers for orientation-preserving homeomorphisms of the circle, cf. [7], [17, Ch.11], [20]. If the system (1.1) is two-dimensional and autonomous (i.e. $A_n \equiv A \in \text{GL}(\mathbb{R}^2)$), then it generates a homeomorphism of the unit circle, which is orientation-preserving for $\det(A) > 0$. If, in addition, no vector rotates by an angle greater than $\pi$, then the rotation number agrees (up to a factor of $2\pi$) with the first angular value; see Section 5.1, Remark 5.3 and Proposition 5.2 for more details. However, such a comparison is no longer possible for a reflection or for matrices which generate rotations of vectors with angles larger than $\pi$. By contrast to rotation numbers, our definition (1.4) avoids to assume or specify any orientation, even when one observes the motion of one-dimensional subspaces (rather than vectors) in a two-dimensional space. Including orientation typically leads to complications in discrete time systems. For example, close to reflections one needs extra analytic information from the system (such as $\det(A_n)$) which we consider as inaccessible to observation. When rotations of vectors larger than $\pi$ occur, our definition takes the smaller of both possible angles. Figure 1.1 illustrates this for a sequence of subspaces which occurs for the linearization along an orbit in the Hénon attractor; see Section 6.3.4 for details. Note that the arrows do not mean orientation but just indicate the succession of measured angles with time progressing outwards.

Figure 1.1: Angles between successive subspaces in the Hénon system.

The theory of rotation numbers for homeomorphisms of the circle has been generalized to so-called rotation sets of toral automorphisms in [19], and a numerical approach appears in [22]. However, there seems to be no connection to the definition (1.4) in higher
Another far-reaching extension of rotation numbers to nonautonomous continuous time systems of arbitrary dimension has been proposed and investigated in [2], [1, Ch.6.5]. The average rotation of vectors is measured within all two-dimensional subspaces (more generally within tangent planes of a manifold) mapped by the system. Orientation is taken into account where counterclockwise refers to positive values. In essence, the flow induced by the given system on the Grassmannian \( G(2, d) \). The concept generalizes to nonlinear random dynamical systems and even leads to a multiplicative ergodic theorem, see [1, Th.6.5.14]. However, the conceptual difference to angular values remains the same as for the classical rotation numbers.

Let us also mention the notion of antieigenvalues and antieigenvectors developed in [13]. They are determined by the maximum angle \( \angle(v, Av) \) by which a given matrix \( A \) can turn a vector \( v \in \mathbb{R}^d \). This corresponds to maximizing the first summand in (1.3), but ergodic averages seem not to have been considered in this theory.

In the following, we summarize some further results of this paper. In Section 3.1 we collect elementary properties of angular values, such as inequalities among them and invariance under special kinematic similarities, see [11] for this notion. Section 5 presents an in-depth study of the autonomous case \( A_n \equiv A \) which turns out to be nontrivial. The conclusions summarized in Theorem 5.7 build on a spectral decomposition (Blocking Lemma 5.5), a special treatment of multiple real eigenvalues (Proposition 5.4), and a detailed analysis of the two-dimensional case (Proposition 5.2). In the two-dimensional case we show that all types of first angular values coincide and provide a rather explicit formula (Proposition 5.2, Theorem 6.1). While real eigenvalues of the matrix lead to a vanishing angular value, complex conjugate ones lead to interesting resonances depending on a skewness parameter; see Figures 6.1, 6.2. In the latter case we use ergodic theory to derive an integral expression for the first angular value when rotation occurs with irrational multiples of \( \pi \), and we reduce the computation to maximizing a finite sum in the rational case. In Section 6 we present a numerical algorithm for the autonomous case based on eigenvalue computations and one-dimensional optimization which avoids failure caused by simple forward iteration. We apply the algorithm to study various systems up to dimension \( 10^4 \), and we confirm numerically the rather subtle behavior in the two-dimensional complex conjugate case.

The method is considerably extended in a forthcoming publication [6] to cope with general nonautonomous systems (1.1) in dimension \( d \geq 2 \) and with angular values of types \( s = 1, 2 \). The algorithm in [6] builds on generalizations of reduction theorems from this paper and on a detailed study which relates angular values to the well-known dichotomy spectrum (also called the Sacker-Sell spectrum, see [25], [3], [23]).

2. Angles of subspaces. In this section we collect some useful results about principal angles between subspaces. In the following, let \( \|v\| = \sqrt{v^\top v} \) denote the Euclidean norm for \( v \in \mathbb{R}^d \) and let \( \mathcal{R}(A), \mathcal{N}(A) \) and \( \sigma(A) \) denote the range, the kernel and the spectrum of a matrix \( A \). Recall the definition of principal angles and principal vectors of two subspaces \( V, W \) of \( \mathbb{R}^d \) of equal dimension from [12, Ch.6.4.3].

**Definition 2.1.** Let \( V, W \) be subspaces of \( \mathbb{R}^d \) of dimension \( s \). Then the principal angles \( 0 \leq \theta_1 \leq \ldots \leq \theta_s \leq \frac{\pi}{2} \) and associated principal vectors \( v_j \in V, w_j \in W \) are defined
recursively for \( j = 1, \ldots, s \) by

\[
\cos(\theta_j) = \max \limits_{v \in V, \|v\| = 1} \max \limits_{w \in W, \|w\| = 1} v^\top w = v_j^\top w_j.
\]

The right-hand side of (2.1) lies in \([0, 1]\), so that \( \theta_j \in [0, \frac{\pi}{2}] \) is uniquely defined by (2.1). While principal angles are unique, principal vectors are not, in general. Let us note that principal angles and principal vectors are also defined for subspaces of different dimension (see [12, Ch.6.4.3]), but this feature will not be used due to our assumption of invertibility.

We further write \( \theta_j = \theta_j(V, W) \) to indicate the dependence on the subspaces, and for the largest angle we introduce the notation

\[
\theta_s(V, W) = \angle(V, W).
\]

If the subspaces \( V \) and \( W \) are one-dimensional we may write

\[
\angle(v, w) = \angle(\text{span}(v), \text{span}(w)), \quad v, w \in \mathbb{R}^d, v, w \neq 0.
\]

Let us also note that the usage of the angle between subspaces varies in the literature. For example, in [1, p.216] this notion is used for \( \sin(\theta_1) \) where \( \theta_1 \) is the smallest angle. Then (2.1) turns into a min-min characterization, and the angle becomes zero if both subspaces share a common direction.

Principal values and vectors can be computed from a singular value decomposition (SVD) as follows.

**Proposition 2.2.** ([12, Algorithm 6.4.3]) Let \( P, Q \in \mathbb{R}^{d \times s} \) be two matrices with orthonormal columns and consider the SVD

\[
P^\top Q = Y \Sigma Z^\top, \quad Y, Z, \Sigma = \text{diag}(\sigma_1, \ldots, \sigma_s) \in \mathbb{R}^{s \times s}, \quad Y^\top Y = I_s = Z^\top Z.
\]

Then the principal angles \( \theta_j \) of \( V = \mathcal{R}(P) \) and \( W = \mathcal{R}(Q) \) satisfy

\[
\sigma_j = \cos(\theta_j), j = 1, \ldots, s,
\]

and principal vectors are given by

\[
PY = \begin{pmatrix} v_1 & \cdots & v_s \end{pmatrix}, \quad QZ = \begin{pmatrix} w_1 & \cdots & w_s \end{pmatrix}.
\]

Since the singular values of \( P^\top Q \) and \( Q^\top P \) agree, principal angles are symmetric with respect to \( V \) and \( W \). In particular, the maximum angle satisfies

\[
\angle(V, W) = \angle(W, V).
\]

In Definition 2.1 the angles between two subspaces of equal dimension are defined recursively. For the computation of the \( j \)-th principal angle, the max-max characterization (2.1) requires knowledge of the principal vectors from index 1 to \( j - 1 \). In the following proposition we state a complementary min-max characterization. It begins with \( \theta_s \) and computes \( \theta_j \) via the known principal vectors for indices \( s \) to \( j + 1 \). The result is motivated by the Hausdorff semi-distance between unit balls and proves to be better suited for the key estimates below. The proof will be given in Appendix A.1.
Proposition 2.3. Let $V, W \subseteq \mathbb{R}^d$ be two $s$-dimensional subspaces. Then the principal angles and principal vectors satisfy for $j = s, \ldots, 1$

\begin{equation}
\cos(\theta_j) = \min_{v \in V, \|v\| = 1} \max_{w \in W, \|w\| = 1} v^T w = v_j^T w_j.
\end{equation}

In particular, the following relation holds

\begin{equation}
\angle(V, W) = \theta_s(V, W) = \max \min_{v \in V, w \in W} \angle(v, w) = \arccos \left( \min_{v \in V} \max_{w \in W} v^T w \right).
\end{equation}

Remark 2.4. A related variational characterization appears in [24, Theorem 3]

\begin{equation}
\cos(\theta_j) = \min_{U \subseteq V, \dim U = j - 1} \max_{x \in U^\perp \cap V, \|x\| = 1} \|x\|^2 \arccos \left( \min_{v \in V} \max_{w \in W} \langle x, y \rangle \right).
\end{equation}

If $j = s$ then $\dim U = s - 1$ and $x \in U^\perp \cap V$ runs through $V$ with $\|x\| = 1$. Therefore, the formula implies (2.4) in case $j = s$, but for $j < s$ the formulas differ.

Next we recall some well-known properties of the Grassmannian,

$G(s, d) = \{ V \subseteq \mathbb{R}^d \text{ is a subspace of dimension } s \}$,

which may be found in [12, Ch.6.4.3], [16], for example.

Proposition 2.5. The Grassmannian $G(s, d)$ is a compact smooth manifold of dimension $s(d - s)$ and a metric space with respect to $d(V, W) = \|P_V - P_W\|$, where $P_V, P_W$ are the orthogonal projections onto $V$ and $W$, respectively, and the formula

\begin{equation}
d(V, W) = \sin(\angle(V, W)), \quad V, W \in G(s, d)
\end{equation}

holds. Furthermore, $\angle(V, W)$ defines an equivalent metric on $G(s, d)$ satisfying

\begin{equation}
\frac{2}{\pi} \angle(V, W) \leq d(V, W) \leq \angle(V, W).
\end{equation}

Some useful geometric estimates for angles of vectors and subspaces follow:

Lemma 2.6. (Angle estimate)

(i) For any two vectors $v, w \in \mathbb{R}^d$ with $\|v\| < \|w\|$ the following holds

\begin{equation}
\tan^2 \angle(v + w, w) \leq \frac{\|v\|^2}{\|w\|^2 - \|v\|^2},
\end{equation}

\begin{equation}
\cos^2 \angle(v + w, w) \geq \frac{\|w\|^2 - \|v\|^2}{\|w\|^2}.
\end{equation}

(ii) Let $V \in G(s, d)$ and $P \in \mathbb{R}^{d, d}$ be such that for some $0 \leq q < 1$

\begin{equation}
\|(I - P)v\| \leq q \|Pv\| \quad \forall \ v \in V.
\end{equation}

Then $\dim(V) = \dim(PV)$ and the following estimate holds

\begin{equation}
\angle(V, PV) \leq \frac{q}{(1 - q^2)^{1/2}}.
\end{equation}
Proof. The first inequality in (2.6) follows from the second via the relation $$\tan^2 \alpha = \frac{1}{\cos^2 \alpha} - 1$$. The second inequality in (2.6) can be rewritten as

$$(v + w)^T w - \|v + w\|^2 (\|w\|^2 - \|v\|^2) \geq 0.$$ 

A short computation shows that the left-hand side agrees with $$((v^T w + \|v\|^2)^2$$ which proves our assertion. The estimate (2.7) shows that $$Pv = 0, v \in V$$ implies $$v = 0$$, hence $$\dim(V) = \dim(PV)$$. Inequality (2.8) follows from (2.6) and the characterization (2.5)

$$\alpha(V, PV) = \max_{v \in V, v \neq 0} \min_{w \in PV, w \neq 0} \frac{\|(I - P)v\|}{\|Pv\|} \leq \frac{1}{\cos \alpha} \leq \frac{2}{1 - \cos^2 \alpha} \leq \frac{4}{3}. \tag{2.9}$$

Remark 2.7. The proof shows that the inequalities in (2.6) are strict for $$v \neq 0$$.

Our final auxiliary result provides an angle-bound for an invertible matrix.

Lemma 2.8. Let $$S \in \text{GL}(\mathbb{R}^d)$$ and $$\kappa = \|S^{-1}\|\|S\|$$ be its condition number. Then the following estimate holds

$$\alpha(SV, SW) \leq \pi \kappa(1 + \kappa) \alpha(V, W) \quad \forall V, W \in \mathcal{G}(s, d), \quad 1 \leq s \leq d. \tag{2.10}$$

Proof. Let us first prove (2.10) for $$s = 1$$. Then we can assume $$V = \text{span}(v), W = \text{span}(w)$$ with $$\|v\| = \|w\| = 1$$ and $$v^T w \geq 0$$. From Proposition 2.5 we have

$$\frac{1}{\pi} \alpha(v, w) \leq \frac{1}{2} d(V, W) = \frac{1}{2} \|vv^T - ww^T\| = \frac{1}{2} \|(v - w)v^T + w(v - w)^T\| 
\leq \|v - w\| = (2(1 - \cos(\alpha(v, w))))^{1/2} = 2\sin\left(\frac{1}{2}\alpha(v, w)\right) \leq \alpha(v, w). \tag{2.10}$$

We apply the first inequality in (2.10) to the image spaces and obtain

$$\alpha(Sv, Sw) = \alpha(\|Sv\|^{-1} Sv, \|Sw\|^{-1} Sw) \leq \pi \|S\| \|Sv\|^{-1} v - \|Sw\|^{-1} w\| 
\leq \pi \|S\| \|Sv\|^{-1} \|S(w - v)\| \leq \pi \|S\| \|Sw\|^{-1} \|S(w - v)\| \leq \pi \kappa(1 + \kappa) \alpha(v, w).$$

Now $$\|Sw\|^{-1}, \|Sv\|^{-1} \leq \|S^{-1}\|$$ and the last inequality from (2.10) lead to

$$\alpha(Sv, Sw) \leq \pi \kappa(1 + \kappa) \|v - w\| \leq \pi \kappa(1 + \kappa) \alpha(v, w).$$

For the general case $$s \geq 1$$ we use (2.10) for all vectors $$v \in V, v \neq 0, w \in W, w \neq 0$$ and then apply the max-min characterization (2.5) from Proposition 2.3. \hfill \blacksquare

3. Basic theory of angular values. For an invertible nonautonomous linear system (1.1) we define the solution operator $$\Phi_A$$ by

$$\Phi_A(n, m) = \begin{cases} A_{n-1} \cdots A_m, & \text{for } n > m, \\
I, & \text{for } n = m, \\
A_n^{-1} \cdots A_{m-1}, & \text{for } n < m. \end{cases}$$

Usually we suppress the dependence on the matrix sequence $$A_n, n \in \mathbb{N}_0$$ and simply write $$\Phi = \Phi_A$$. However, in Section 4 we consider matrix families generated by a linear random dynamical system for which the dependence on the family is essential.
\subsection*{3.1. Definitions and elementary properties.} In the following we consider various ways of defining the average angular rotation that the system (1.1) exerts on subspaces of a fixed dimension. For this we use the notion of angles of subspaces from Section 2.

We reconsider a rigid rotation (1.5) as a simple motivating example, but now we allow $0 \leq \varphi \leq \pi$. For $v \in \mathbb{R}^2$, $v \neq 0$ and $j \in \mathbb{N}$ one obtains with Proposition 2.2 that

$$\angle(v, T_{\varphi}v) = \angle(T_{\varphi}^{-1}v, T_{\varphi}^j v) = \arccos(|\cos(\varphi)|) = \min(\varphi, \pi - \varphi).$$

Hence we obtain for $n \in \mathbb{N}$ the arithmetic mean

$$\sup_{v \in \mathbb{R}^2} \frac{1}{n} \sum_{j=1}^n \angle(T_{\varphi}^{-1}v, T_{\varphi}^j v) = \sup_{V \in \mathcal{G}(1,2)} \frac{1}{n} \sum_{j=1}^n \angle(\Phi(j - 1, 0)V, \Phi(j, 0)V) = \min(\varphi, \pi - \varphi)$$

and the same value for both types of limits $\sup_{V \in \mathcal{G}(1,2)} \lim_{n \to \infty}$ and $\lim_{n \to \infty} \sup_{V \in \mathcal{G}(1,2)}$.

For general systems however, it turns out that the limit does not necessarily commute with the supremum, and sometimes the limit does not even exist. Therefore, we introduce several different types of angular values.

\textbf{Definition 3.1.} Let the invertible nonautonomous system (1.1) be given. For every $s \in \{1, \ldots, d\}$ define the quantities

$$a_{k+1, k+n}(V) = \sum_{j=k+1}^{k+n} \angle(\Phi(j - 1, 0)V, \Phi(j, 0)V) \quad n \in \mathbb{N}, \; k \in \mathbb{N}_0, \; V \in \mathcal{G}(s, d).$$

i) The upper resp. lower $s$-th \textbf{inner angular value} is defined by

\begin{equation}
\tilde{\theta}_s = \limsup_{n \to \infty} \frac{1}{n} \sum_{V \in \mathcal{G}(s, d)} a_{1,n}(V), \quad \underline{\theta}_s = \liminf_{n \to \infty} \frac{1}{n} \sum_{V \in \mathcal{G}(s, d)} a_{1,n}(V).
\end{equation}

ii) The upper resp. lower $s$-th \textbf{outer angular value} is defined by

\begin{equation}
\tilde{\hat{\theta}}_s = \sup_{V \in \mathcal{G}(s, d)} \limsup_{n \to \infty} \frac{1}{n} \sum_{V \in \mathcal{G}(s, d)} a_{1,n}(V), \quad \underline{\hat{\theta}}_s = \sup_{V \in \mathcal{G}(s, d)} \liminf_{n \to \infty} \frac{1}{n} \sum_{V \in \mathcal{G}(s, d)} a_{1,n}(V).
\end{equation}

iii) The upper resp. lower $s$-th \textbf{uniform inner angular value} is defined by

\begin{equation}
\tilde{\theta}_{[s]} = \limsup_{n \to \infty} \frac{1}{n} \sup_{V \in \mathcal{G}(s, d)} \sup_{k \in \mathbb{N}_0} a_{k+1,k+n}(V),
\end{equation}

\begin{equation}
\underline{\theta}_{[s]} = \liminf_{n \to \infty} \frac{1}{n} \sup_{V \in \mathcal{G}(s, d)} \inf_{k \in \mathbb{N}_0} a_{k+1,k+n}(V).
\end{equation}

iv) The upper resp. lower $s$-th \textbf{uniform outer angular value} is defined by

\begin{equation}
\tilde{\hat{\theta}}_{[s]} = \sup_{V \in \mathcal{G}(s, d)} \limsup_{n \to \infty} \frac{1}{n} \sup_{k \in \mathbb{N}_0} a_{k+1,k+n}(V),
\end{equation}

\begin{equation}
\underline{\hat{\theta}}_{[s]} = \sup_{V \in \mathcal{G}(s, d)} \limsup_{n \to \infty} \frac{1}{n} \sup_{k \in \mathbb{N}_0} a_{k+1,k+n}(V).
\end{equation}

\textbf{Remark 3.2.} In case $s = d$, all angular values are zero since the invertible system keeps the space $V = \mathbb{R}^d$ fixed and since $\angle(\mathbb{R}^d, \mathbb{R}^d) = 0$. 

8
Our guiding principle in forming these quantities is to seek the subspace $V$ which maximizes an angular value. The notions of 'upper' and 'lower' are motivated by the possible gap between $\text{lim sup}$ and $\text{lim inf}$ while 'outer' and 'inner' result from the noncommuting $\text{lim sup}$ and $\text{lim inf}$. Finally, the corresponding uniform angular values (and their 'lower' and 'upper' variants) become relevant when passing from autonomous to nonautonomous systems; see Sections 3.2 and 5.

Clearly, the $\text{lim sup}$ and $\text{lim inf}$ in (3.1), (3.2), (3.3) are finite due to the boundedness of the angles. In Section 4 we prove that the $\text{lim sup}$ and $\text{lim inf}$ in (3.1) actually become limits in the setting of random dynamical systems. Let us further mention that the supremum for both quantities in (3.1) can be replaced by a maximum since $a_{1,n}(V)$ depends continuously on $V$ in the compact space $\mathcal{G}(s,d)$.

In the following lemma we show that the limits in (3.4) always exist and that the $\text{lim sup}$ in the definition (3.3) of $\hat{\theta}_s$ is in fact a limit. Further, we collect some easy relations between the various angular values.

**Lemma 3.3.** The limits in the definition (3.4) of the uniform outer angular values exist in $[0, \frac{\pi}{2}]$ and the $\text{lim sup}$ in the definition of $\hat{\theta}_s$ is a limit. Moreover, the following relations hold for all $s = 1, \ldots, d$:

\[
\begin{align*}
\theta_s &\leq \theta_s \leq \hat{\theta}_s \leq \hat{\theta}_s \\
\theta_s &\leq \theta_s \leq \hat{\theta}_s \leq \hat{\theta}_s
\end{align*}
\]  

(3.5)

For the smallest and the largest value in this diagram we have the estimate

\[
\sup_{V \in \mathcal{G}(s,d)} \inf_{k \in \mathbb{N}_0} \angle(\Phi(k,0)V, A_k \Phi(k,0)V) \leq \hat{\theta}_s \leq \hat{\theta}_s \leq \sup_{V \in \mathcal{G}(s,d)} \inf_{k \in \mathbb{N}_0} \angle(V, A_k V).
\]  

(3.6)

**Proof.** For every $V \in \mathcal{G}(s,d)$, the sequence $a_n(V) = \sup_{k \in \mathbb{N}_0} a_{k+1,k+n}(V)$ lies in $[0, \frac{\pi}{2}]$ and is subadditive

\[
a_{n+m}(V) = \sup_{k \in \mathbb{N}_0} (a_{k+1,k+n}(V) + a_{k+n+1,k+n+m}(V))
\]

\[
\leq \sup_{k \in \mathbb{N}_0} a_{k+1,k+n}(V) + \sup_{n \geq n} a_{k+n+1,k+n+m}(V) \leq a_n(V) + a_m(V).
\]

By Fekete’s subadditive lemma [9, Lemma 4.2.7] this ensures

\[
\lim_{n \to \infty} \frac{1}{n} a_n(V) = \inf_{n \in \mathbb{N}} \frac{1}{n} a_n(V) \in [0, \frac{\pi}{2}].
\]

In a similar way, the sequence $a_n = \sup_{V \in \mathcal{G}(s,d)} a_n(V)$ turns out to be subadditive, which shows that $\text{lim sup} = \text{lim}$ for the first quantity in (3.3). Further, the sequence $\alpha_n(V) = \inf_{k \in \mathbb{N}_0} a_{k+1,k+n}(V)$ turns out to be superadditive, i.e. $\alpha_{n+m}(V) \geq \alpha_n(V) + \alpha_m(V)$ for $n, m \in \mathbb{N}$, and thus

\[
\lim_{n \to \infty} \frac{1}{n} \alpha_n(V) = \sup_{n \in \mathbb{N}} \frac{1}{n} \alpha_n(V) \in [0, \frac{\pi}{2}].
\]

Next we prove the inequalities $\theta_s \leq \hat{\theta}_s \leq \hat{\theta}_s$,

\[
\begin{align*}
\theta_s &= \sup_{V \in \mathcal{G}(s,d)} \liminf_{n \to \infty} \frac{1}{n} a_{1,n}(V) \leq \sup_{V \in \mathcal{G}(s,d)} \limsup_{n \to \infty} \frac{1}{n} a_{1,n}(V) = \hat{\theta}_s \\
&\leq \limsup_{n \to \infty} \frac{1}{n} a_{1,n}(V) = \hat{\theta}_s \leq \limsup_{n \to \infty} \frac{1}{n} a_{k+1,k+n}(V) = \hat{\theta}_s.
\end{align*}
\]
The remaining assertions in (3.5) follow in a similar way. Finally, note that Fekete’s lemma leads to the representations
\[
\sup_{V \in \mathcal{G}(s,d)} \sup_{n \in \mathbb{N}} \frac{1}{n} \inf_{k \in \mathbb{N}_0} a_{k+1,k+n}(V) = \tilde{\theta}_1 \leq 2 \tilde{\theta}_0 = \inf_{n \in \mathbb{N}} \sup_{V \in \mathcal{G}(s,d)} \sup_{k \in \mathbb{N}_0} a_{k+1,k+n}(V).
\]
The inequalities (3.6) then follow by setting \( n = 1 \) in \( \sup_n \) and \( \inf_n \).

We extend the motivating example (1.5) and analyze in detail the outer angular values of the 3-dimensional system defined by

\[
A_n = A = \begin{pmatrix}
\cos(\varphi) & -\sin(\varphi) & 0 \\
\sin(\varphi) & \cos(\varphi) & 0 \\
0 & 0 & 2
\end{pmatrix}, \quad n \in \mathbb{N}_0, \quad 0 < \varphi \leq \frac{\pi}{2}.
\]

Denote by \( e_j \) the \( j \)-th unit vector in \( \mathbb{R}^3 \). For \( v \in \text{span}(e_1, e_2) \), we get, cf. (1.5), that \( \angle(A^{i-1}v, A^iv) = \varphi \) for all \( i \in \mathbb{N} \). For \( v \in \text{span}(e_3) \) one has \( \angle(A^{i-1}v, A^iv) = 0 \), \( i \in \mathbb{N} \). Next, we take a vector with components in both relevant subspaces. This vector is pushed under iteration with \( A \) towards the most unstable direction \( e_3 \). Thus, we expect that the angle between two subsequent iterates converges to 0. The following estimate proves that this convergence is indeed geometric. Consider \( v = (\xi) \) with \( 0 \neq z \in \mathbb{R}^2 \). From the triangle inequality and the estimate (2.6) in Lemma 2.6 we find a constant \( C > 0 \) such that for all \( i \in \mathbb{N} \)

\[
\angle(A^{i-1}v, A^iv) = \angle \left( \left( \frac{T_i^{i-1}z}{2^{i-1}} \right), \left( \frac{T_i^iz}{2^i} \right) \right) = \angle \left( \left( \frac{2^{1-i}T_i^{i-1}z}{2^i} \right), \left( \frac{2^{-i}T_i^iz}{2^i} \right) \right)
\]

\[
\leq \angle \left( \left( \frac{2^{1-i}T_i^{i-1}z}{2^i} \right), \left( \frac{0}{1} \right) \right) + \angle \left( \left( \frac{0}{1} \right), \left( \frac{2^{-i}T_i^iz}{2^i} \right) \right)
\]

\[
\leq \tan \angle \left( \left( \frac{2^{1-i}T_i^{i-1}z}{2^i} \right), \left( \frac{0}{1} \right) \right) + \tan \angle \left( \left( \frac{2^{-i}T_i^iz}{2^i} \right), \left( \frac{0}{1} \right) \right)
\]

\[
\leq C \cdot 2^{-i}.
\]

Thus

\[
\frac{1}{n} \sum_{i=1}^{n} \angle(A^{i-1}v, A^iv) \leq \frac{1}{n} \sum_{i=1}^{\infty} C \cdot 2^{-i} = \frac{2C}{n} \to 0 \text{ as } n \to \infty.
\]

As a consequence, all first outer angular values from Definition 3.1 coincide and have the value \( \varphi \), see Figure 3.1 and Theorem 5.7 for the inner angular values.

For analyzing the second outer angular values, we first note that for all \( V \in \mathcal{G}(2,3) \) there exists a \( u \in \text{span}(e_1, e_2) \) such that \( V = \text{span}(u, v) \) with \( v \in \mathbb{R}^3 \). Without loss of generality, we assume that \( u = e_1 \). We observe for \( v \in \text{span}(e_1, e_2) \) that \( a_{1,n}(V) = 0 \) and for \( v \in \text{span}(e_3) \), we obtain \( a_{1,n}(V) = \varphi \). Next, we consider the mixed case \( v = (z_1 \ 2z_2 \ 1) \) \( \perp \), with \( 0 \neq z \in \mathbb{R}^2 \). Let \( W = \text{span}(e_1, e_3) \) then we get for \( i \in \mathbb{N} \)

\[
\angle(A^{i-1}V, A^iV) \leq \angle(A^{i-1}V, A^{i-1}W) + \angle(A^{i-1}W, A^iW) + \angle(A^iW, A^iV).
\]

The second term is equal to \( \varphi \) for all \( i \in \mathbb{N} \). We conclude that all second outer angular values coincide with \( \varphi \) by showing that the first and third term converge to zero with a
geometric rate. Note that for $i \in \mathbb{N}_0$ we have
\[
A^i V = \text{span}(A^i e_1, A^i e_3 + A^i (z_1 \ z_2 \ 0)^\top),
\]
\[
A^i W = \text{span}(A^i e_1, e_3 + 2^{-i}A^i (z_1 \ z_2 \ 0)^\top),
\]

With $P_i = I + Q_i$, $Q_i = 2^{-i}A^i \begin{pmatrix} 0 & 0 & z_1 \\ 0 & 0 & z_2 \\ 0 & 0 & 0 \end{pmatrix}$ it follows that $A^i V = P_i A^i W$. Furthermore, we find an $i$-independent constant $C > 0$ such that $\| (I - P_i)v \| = \| Q_i v \| \leq 2^{-i}C P_i v \|$ for all $v \in \mathbb{R}^3$. Thus, Lemma 2.6, (ii) applies for sufficiently large $i \in \mathbb{N}$ and provides the estimate
\[
\angle(A^i V, A^i W) \leq 2^{-i} \frac{C}{(1 - 2^{-i}C)^2}
\]
which completes the proof.

![Figure 3.1: First and second angular values for the motivating three-dimensional system (3.7).](image)

In general, equality does not hold in (3.5). This phenomenon is illustrated in Section 3.2 by Examples 3.9 and 3.10. However, angular values do agree when the angles of iterates or their averages occurring in Definition 3.1 have some uniformity properties. For this purpose let us introduce for $n \in \mathbb{N}$ the functions
\[
b_n : \mathcal{G}(s, d) \to \mathbb{R}, \quad b_n(V) = \angle(\Phi(n - 1, 0)V, \Phi(n, 0)V),
\]
and recall $a_{1,n}(V) = \sum_{j=1}^n b_j(V)$ from Definition 3.1. Let us also recall the notion of uniform almost periodicity for a sequence of functions.

**Definition 3.4.** Given a set $\mathcal{V}$ and a Banach space $(\mathcal{W}, \| \cdot \|)$. A sequence of mappings $b_n : \mathcal{V} \to \mathcal{W}$, $n \in \mathbb{N}$ is called uniformly almost periodic if
\[
\forall \varepsilon > 0 \ \exists P \in \mathbb{N} : \forall V \in \mathcal{V} \ \forall \ell \in \mathbb{N} \ \exists p \in \{\ell, \ldots, \ell + P\} : \forall n \in \mathbb{N} : \|b_n(V) - b_{n+p}(V)\| \leq \varepsilon.
\]
Remark 3.5. Our definition is slightly weaker than the standard notion ([21, Ch.4.1]) which requires for each \( \varepsilon > 0 \) the existence of a relatively dense set \( P \subset \mathbb{N} \) such that

\[
\forall n \in \mathbb{N} \forall p \in P \forall V \in \mathcal{V} : \|b_n(V) - b_{n+p}(V)\| \leq \varepsilon.
\]

This is more restrictive, since the choice of \( p \in \{ \ell, \ldots, \ell + P \} \cap P \) is uniform in \( V \).

The following proposition will be used repeatedly when determining angular values for the two-dimensional case; see Proposition 5.2.

Proposition 3.6. The following statements hold for all \( s \in \{ 1, \ldots, d \} \).

(a) If the functions \( \frac{1}{s} a_{1,n} : \mathcal{G}(s, d) \to \mathbb{R} \) converge uniformly to the constant function \( \varphi \in [0, \frac{\pi}{2}] \) as \( n \to \infty \), then all nonuniform angular values coincide, i.e., \( \hat{\theta}_s = \hat{\theta}_s = \bar{\theta}_s = \bar{\theta}_s = \hat{\theta}_s = \hat{\theta}_s = \hat{\theta}_s = \hat{\theta}_s \).

(b) If the functions \( b_n, n \in \mathbb{N} \) are uniformly almost periodic, then all angular values coincide,

\[
\theta_{[s]} = \theta_s = \hat{\theta}_s = \bar{\theta}_s = \bar{\theta}_s = \hat{\theta}_s = \hat{\theta}_s.
\]

Proof. The claim in (a) is clear since \( \limsup \) and \( \liminf \) in (3.2) are limits and the supremum is continuous w.r.t. uniform convergence.

Lemma 3.3 shows that it suffices for (b) to prove \( \bar{\theta}_{[s]} \leq \theta_{[s]} \). By the definition (3.3) we find for every \( \varepsilon > 0 \) a number \( N_1 \in \mathbb{N} \) and for all \( n \geq N_1 \) elements \( V_n \in \mathcal{G}(s, d), k_n \in \mathbb{N} \) such that

\[
\left| \frac{1}{n} \sum_{j=1}^{n} b_j(V_N) - \frac{1}{N} \sum_{j=1}^{N} b_{j+k_n}(V_N) \right| \leq \frac{\varepsilon}{2}.
\]

From Lemma A.1 we obtain \( N = N(\varepsilon) \in \mathbb{N} \), \( N \geq N_1 \) such that for all \( n \geq N, h \in \mathbb{N}_0 \)

\[
\left| \frac{1}{n} \sum_{j=1}^{n} b_j(V_N) - \frac{1}{N} \sum_{j=1}^{N} b_{j+k_n}(V_N) \right| + \left| \frac{1}{n} \sum_{j=1}^{n} b_j(V_N) - \frac{1}{n} \sum_{j=1}^{n} b_{j+h}(V_N) \right| \leq \frac{\varepsilon}{2}.
\]

Combining these results yields for all \( h \in \mathbb{N}_0, n \geq N \):

\[
\bar{\theta}_{[s]} \leq \frac{1}{n} \sum_{j=1}^{n} b_j(V_N) + \left| \frac{1}{n} \sum_{j=1}^{n} b_j(V_N) - \frac{1}{n} \sum_{j=1}^{n} b_{j+h}(V_N) \right| + \left| \frac{1}{n} \sum_{j=1}^{n} b_{j+k_n}(V_N) - \frac{1}{n} \sum_{j=1}^{n} b_{j+k_n}(V_N) \right| + \left| \frac{1}{n} \sum_{j=1}^{n} b_{j+k_n}(V_N) - \frac{1}{N} \sum_{j=1}^{N} b_{j+k_n}(V_N) \right| + \left| \frac{1}{n} \sum_{j=1}^{n} b_{j+k_n}(V_N) - \frac{1}{n} \sum_{j=1}^{n} b_{j+k_n}(V_N) \right| \leq \frac{\varepsilon}{2} + \frac{\varepsilon}{2} + \frac{1}{n} \sum_{j=1}^{n} b_{j+h}(V_N).
\]

Taking the infimum over \( h \) and the limit \( n \to \infty \) (see Lemma 3.3 for its existence) shows that there exists \( V(\varepsilon) := V_{N(\varepsilon)} \in \mathcal{G}(s, d) \) satisfying

\[
\bar{\theta}_{[s]} - \varepsilon \leq \liminf_{n \to \infty} \inf_{h \in \mathbb{N}_0} \frac{1}{n} \sum_{j=1}^{n} b_{j+h}(V(\varepsilon)).
\]

Thus we deduce

\[
\bar{\theta}_{[s]} - \varepsilon \leq \sup_{V \in \mathcal{G}(s, d)} \liminf_{n \to \infty} \inf_{h \in \mathbb{N}_0} \frac{1}{n} \sum_{j=1}^{n} b_{j+h}(V) = \bar{\theta}_{[s]} \leq \bar{\theta}_{[s]}.
\]
Next, we apply a kinematic similarity, induced by a transformation $\tilde{u}_n = Q_n u_n$ with $Q_n \in \text{GL}(\mathbb{R}^d)$ to (1.1), i.e. we consider

$$\tilde{u}_{n+1} = \tilde{A}_n \tilde{u}_n, \quad \tilde{A}_n = Q_{n+1} A_n Q_n^{-1},$$

and ask when angular values or the whole spectrum remains unchanged.

**Proposition 3.7. (Invariance of angular values)**

(i) Assume that the transformation matrices are of the form $Q_n = r_n Q$, $n \in \mathbb{N}$ with $r_n \in \mathbb{R}$, $r_n \neq 0$ and $Q \in \mathbb{R}^{d \times d}$ orthogonal. Then the angular values of (1.1) and (3.8) agree.

(ii) Assume constant transformation matrices $Q_n = Q, n \in \mathbb{N}_0$ with $Q$ invertible. If any of the values $\theta_s$ in Definition 3.1 vanishes for the system (1.1) then the same angular value vanishes for the transformed system (3.8).

**Proof.** In case (i) one readily verifies that the solution operators $\tilde{\Phi}$ and $\Phi$ of (3.8) and (1.1) are related by

$$\tilde{\Phi}(j,0)Q = r_j r_0 Q \Phi(j,0), \quad j \in \mathbb{N}_0.$$  

The result then follows from the invariance of angles under scalings and orthogonal transformations (cf. Proposition 2.2)

$$\angle(\tilde{\Phi}(j-1,0)QV, \tilde{\Phi}(j,0)QV) = \angle(r_j^{-1} r_0^{-1} Q \Phi(j-1,0)V, r_j r_0 \Phi(j,0)V)$$

$$= \angle(\Phi(j-1,0)V, \Phi(j,0)V).$$

For case (ii) the relation is $\tilde{\Phi}(j,0)Q = Q \Phi(j,0)$ and the assertion follows from the angle-boundness (2.9) of the matrix $S = Q$.

Finally, we discuss an invariance property of maximizers which occur with the outer angular values. Starting with the difference equation (1.1), we define for $n \in \mathbb{N}_0$ the matrices $A_n(\eta) := A_{n+\eta}$. Denote by $\Phi^\dag_\eta$ the solution operator of the shifted difference equation

$$u_{n+1} = A_{n+\eta} u_n, \quad n \in \mathbb{N}_0$$

and observe that for all $n, m, \eta \in \mathbb{N}_0$

$$\Phi^\dag_\eta(n,m) = \Phi(n + \eta, m + \eta).$$

Let $\hat{\theta}_s(\eta)$ be the $s$-th upper outer angular value for (3.9). The corresponding maximizers that occur with the outer values are given by

$$\hat{V}_s(\eta) = \left\{ V \in \mathcal{G}(s,d) : \hat{\theta}_s(\eta) = \limsup_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} \angle(\Phi^\dag_\eta(j-1,0)V, \Phi^\dag_\eta(j,0)V) \right\}.$$ 

Note that this set may be empty. We obtain the following invariance.
Proposition 3.8. Let $A_n \in \mathbb{R}^{d,d}$, $n \in \mathbb{N}_0$ be invertible matrices. Then the following relation holds for all $\eta \in \mathbb{N}$,

\begin{equation}
A_\eta \hat{V}_s(\eta) = \hat{V}_s(\eta + 1).
\end{equation}

Proof. Fix $\eta \in \mathbb{N}$ and let $V \in \mathcal{G}(s,d)$. Then we get

\[
\frac{1}{n} \sum_{j=1}^{n} \angle \left( \Phi^+_{\eta+1}(j,0) A_\eta V, \Phi^+_{\eta+1}(j,0) A_\eta V \right)
= \frac{1}{n} \sum_{j=1}^{n} \angle \left( \Phi(j+\eta,\eta+1) A_\eta V, \Phi(j+\eta+1,\eta+1) A_\eta V \right)
= \frac{1}{n} \sum_{j=1}^{n} \angle \left( \Phi(j+\eta) V, \Phi(j+\eta+1,\eta) A_\eta V \right)
= \frac{n+1}{n+1} \left( \sum_{j=1}^{n} \angle \left( \Phi^+_{\eta}(j,0) V, \Phi^+_{\eta}(j,0) V \right) - \angle \left( V, \Phi^+_{\eta}(1,0) V \right) \right).
\]

Taking $\limsup$ as $n \to \infty$ we have

\[
\limsup_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} \angle \left( \Phi^+_{\eta+1}(j,0) A_\eta V, \Phi^+_{\eta+1}(j,0) A_\eta V \right)
= \limsup_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} \angle \left( \Phi^+_{\eta}(j,0) V, \Phi^+_{\eta}(j,0) V \right).
\]

In case $\hat{V}_s(\eta) = \emptyset$ then $\hat{V}_s(\eta + 1) = \emptyset$ and (3.10) is trivial. Otherwise, the invertibility of $A_\eta$ yields

\[
V \in \hat{V}_s(\eta) \Leftrightarrow A_\eta V \in \hat{V}_s(\eta + 1)
\]

which proves (3.10).

A corresponding result also holds for lower outer angular values as well as for uniform outer angular values.

3.2. Some nonautonomous key examples. Upper, lower, uniform respectively non-uniform outer and inner angular values do not coincide in general. The following examples illustrate this fact.

First, we construct an example which possesses different upper, lower and uniform angular values. A related example in continuous time can be found in [8, Example 2.2]. There, the authors illustrate that the Lyapunov spectrum may be a proper subset of the Sacker-Sell spectrum and that generally both spectra do not consist of isolated points only.

Example 3.9. Fix $0 \leq \varphi_0 < \varphi_1 \leq \frac{\pi}{2}$ and let $T_\varphi := \begin{pmatrix} \cos \varphi & -\sin \varphi \\ \sin \varphi & \cos \varphi \end{pmatrix}$. For $n \in \mathbb{N}_0$, we define

\[
A_n = \begin{cases} 
T_{\varphi_0}, & \text{for } n = 0 \lor n \in \bigcup_{\ell=1}^{\infty} [2^{2\ell-1}, 2^{2\ell} - 1] \cap \mathbb{N}, \\
T_{\varphi_1}, & \text{otherwise}.
\end{cases}
\]

14
Table 3.1 illustrates this construction.

Inner and outer angular values coincide for the nonautonomous difference equation

\[ u_{n+1} = A_n u_n, \quad n \in \mathbb{N}_0, \]

since all one-dimensional subspaces rotate through the same angle.

Denote by \( p_\ell \) the number of occurrences of \( \mathbf{T}_\varphi_1 \) in \( (A_n)_{0 \leq n \leq \ell} \). One observes for \( n \in \mathbb{N} \) that

\[ p_{2^{2n-1}-1} = \frac{1}{3} (4^n - 1) = p_{2^n - 1} \]

and

\[ \lim_{n \to \infty} \frac{1}{2^{2n-1} - 1} p_{2^{2n-1}-1} = \frac{2}{3}, \quad \lim_{n \to \infty} \frac{1}{2^{2n} - 1} p_{2^{2n}-1} = \frac{1}{3}. \]

Thus, we obtain

\[ \theta_1 = \theta_1 = \frac{2}{3} \varphi_0 + \frac{1}{3} \varphi_1, \quad \bar{\theta}_1 = \bar{\theta}_1 = \frac{1}{3} \varphi_0 + \frac{2}{3} \varphi_1. \]

For each \( n \in \mathbb{N} \), we find infinitely many indices \( \nu \in \mathbb{N} \) such that \( A_\nu + \ell = \mathbf{T}_\varphi_0 \) (resp. \( A_\nu + \ell = \mathbf{T}_\varphi_1 \)) for all \( \ell = 0, \ldots, n - 1 \). As a consequence, the diagram (3.5) from Lemma 3.3 reads

\[ \varphi_0 = \theta_1 < \frac{2}{3} \varphi_0 + \frac{1}{3} \varphi_1 = \theta_1 < \frac{1}{3} \varphi_0 + \frac{2}{3} \varphi_1 = \bar{\theta}_1 < \bar{\theta}_1 = \varphi_1. \]

Although inner and outer angular values coincide for Example 3.9, this coincidence is in general not true. We discuss the following example.

**Example 3.10.** Let

\[ C := \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad R := \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}. \]

In case of the reflection \( R \), we observe for \( v = \begin{pmatrix} \cos \theta \\ \sin \theta \end{pmatrix}, \theta \in [0, \frac{\pi}{2}] \) that

\[ \angle(v, Rv) = \begin{cases} 2\theta, & \text{for } 0 \leq \theta \leq \frac{\pi}{4}, \\ \pi - 2\theta, & \text{for } \frac{\pi}{4} < \theta \leq \frac{\pi}{2} \end{cases} \]

and the maximal angle is achieved at \( v \in \text{span} \{ \left\{ \frac{1}{1} \right\} \}. \)

For \( n \in \mathbb{N}_0 \), we define

\[ A_n := \begin{cases} R, & \text{for } n \in \bigcup_{\ell=1}^{\infty} [2 \cdot 2^\ell - 4, 3 \cdot 2^\ell - 5], \\ C, & \text{otherwise}. \end{cases} \]
Table 3.2 illustrates this construction.

We prove that inner and outer angular values of the nonautonomous difference equation

$$u_{n+1} = A_n u_n, \quad n \in \mathbb{N}_0$$

do not coincide. First we show that $\hat{\theta}_1 = 0$. Let

$$V_0 := \text{span}\left(\frac{\cos \theta}{\sin \theta}\right), \quad b_j(\theta) = \angle(\Phi(j-1,0)V_0, \Phi(j,0)V_0).$$

For $\theta \in \{0, \frac{\pi}{2}\}$ we get $b_j(\theta) = 0$ for all $j \in \mathbb{N}$. In the case $\theta \in (0, \frac{\pi}{2})$ we observe that $\Phi(j,0)V_0 \to V_0$ as $j \to \infty$. Thus for each $\varepsilon > 0$ there exists an $N \in \mathbb{N}$ such that $b_j(\theta) \leq \varepsilon$ for all $j \geq N$. As a consequence we get for $n$ sufficiently large

$$\frac{1}{n} \sum_{j=1}^{n} b_j(\theta) = \frac{1}{n} \left(\sum_{j=1}^{N-1} b_j(\theta) + \sum_{j=N}^{n} b_j(\theta)\right) \leq \frac{1}{n} \left((N-1)\frac{\pi}{2} + (n+1-N)\varepsilon\right) \leq 2\varepsilon$$

and this shows

$$\hat{\theta}_1 = \sup_{V \in G(1,2)} \limsup_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} \angle(\Phi(j-1,0)V, \Phi(j,0)V) = 0.$$  

Similarly, all outer angular values are zero.

Next, we determine an estimate for the upper inner angular value. We claim that $\bar{\theta}_1 \geq \frac{\pi}{6}$.

For $\ell \in \mathbb{N}$ let $p_\ell := 3 \cdot 2^\ell - 5$. Note that the matrix $C$ appears $2^\ell - 2$ times in $(A_n)_{0 \leq n \leq p_\ell}$ and $R$ appears $2^\ell$ times in $(A_n)_{p_\ell < n \leq p_\ell}$.

Let $V(\ell) := \text{span}\{C^{-2^{\ell}+2}(\frac{1}{2})\}$. We obtain

$$\hat{\theta}_1 = \limsup_{n \to \infty} \sup_{V \in G(1,2)} \frac{1}{n} \sum_{j=1}^{n} \angle(\Phi(j-1,0)V, \Phi(j,0)V)$$

$$\geq \limsup_{\ell \to \infty} \frac{1}{p_\ell + 1} \sum_{j=1}^{p_\ell+1} \angle(\Phi(j-1,0)V(\ell), \Phi(j,0)V(\ell))$$

$$\geq \limsup_{\ell \to \infty} \frac{1}{p_\ell + 1} \frac{2\ell \pi}{2} = \lim_{\ell \to \infty} \frac{2\ell}{3 \cdot 2^\ell - 4} \cdot \frac{\pi}{2} = \frac{\pi}{6}.$$  

We obtain estimates for $\theta_1$ by analyzing the subsequence $n = p_\ell - 2^\ell + 1$ for $\ell \in \mathbb{N}$. These indices detect the end of each block of $C$s. In particular, we observe that $\frac{\pi}{12} \leq \theta_1 < \frac{\pi}{6}$.

Similarly, we compute all angular values and the diagram (3.5) from Lemma 3.3 reads

$$0 = \theta_{[1]} = 0 = \theta_1 = 0 = \hat{\theta}_1 = \hat{\theta}_{[1]} = 0$$

$$0 = \theta_{[1]} < \frac{\pi}{12} \leq \theta_1 < \frac{\pi}{6} \leq \hat{\theta}_1 < \hat{\theta}_{[1]} = \frac{\pi}{6}.$$
4. Angular values of random linear cocycles. Following [1, Ch.3.3.1] we consider a probability space \((\Omega, \mathcal{F}, \mathbb{P})\) and let \(T : \Omega \to \Omega\) be a measurable, \(\mathbb{P}\)-preserving, ergodic transformation. Let \(A : \Omega \to \text{GL}(\mathbb{R}^d)\) and set \(A^{(n)}_\omega = A(T^{n-1}\omega) \cdots A(T\omega)A(\omega)\). Note that \(A^{(n)}_\omega\) corresponds to a random solution operator \(\Phi(n, 0, \omega)\) in the setting of Section 3; cf. [1, (3.3.2)]. In analogy to the right-hand side of (1.3), for \(n \geq 1\), define for \(s \in \{1, \ldots, d\}\) and \(V \in \mathcal{G}(s, d)\)

\[
a_n(\omega, V) = \sum_{j=0}^{n-1} \angle(A^{(j)}V, A^{(j+1)}V).
\]

Define a skew product \(\tau : \Omega \times \mathcal{G}(s, d) \to \mathbb{R}\) by \(\tau(\omega, V) = (T\omega, A(\omega)V)\) and \(f : \Omega \times \mathcal{G}(s, d) \to \mathbb{R}\) by \(f(\omega, V) = \angle(V, A(\omega)V)\). One has the Birkhoff sum representation:

\[
a_n(\omega, V) = \sum_{j=0}^{n-1} f(\tau^j(\omega, V)).
\]

The following result provides general conditions for the angular value limits to be independent of the initial condition \(\omega\) and reference subspace \(V\).

**Theorem 4.1.** Suppose \(\tau\) preserves an ergodic probability measure \(\mu\) on \(\Omega \times \mathcal{G}(s, d)\), where \(\mu\) has marginal \(\mathbb{P}\) on \(\Omega\); that is, \(\mu(\cdot, \mathcal{G}(s, d)) = \mathbb{P}\). Then there is a \(\theta_s \in [0, \pi/2]\) satisfying

\[
\theta_s = \lim_{n \to \infty} \frac{1}{n} a_n(\omega, V) = \int_{\Omega \times \mathcal{G}(s, d)} \angle(V, A(\omega)V) \, d\mu(\omega, V),
\]

for \(\mu\)-almost every \((\omega, V) \in \Omega \times \mathcal{G}(s, d)\).

**Proof.** This follows immediately from Birkhoff’s ergodic theorem and ergodicity of \(\tau\).

On the one hand, \(\lim_{n \to \infty} \frac{1}{n} a_n(\omega, V)\) does not depend on \(\omega\) and on \(V\) for \(\mu\)-almost every \((\omega, V) \in \Omega \times \mathcal{G}(s, d)\) under the assumptions of Theorem 4.1. On the other hand, our motivating example (3.7) shows that angular values are generally achieved for a nongeneric set of subspaces for which any reasonable measure in \(\mathcal{G}(s, d)\) vanishes. Therefore, in analogy to Section 3.1, we consider angular values of a random linear cocycle w.r.t. \(\omega \in \Omega\) and ask for extreme values w.r.t. \(V \in \mathcal{G}(s, d)\).

**Theorem 4.2.** Let \(T : \Omega \to \Omega\) be a measurable, \(\mathbb{P}\)-preserving, ergodic transformation and let \(A : \Omega \to \text{GL}(\mathbb{R}^d)\). Then the following assertions hold.

1. For \(\mathbb{P}\)-a.e. \(\omega\), the limit

\[
\bar{\theta}_s := \lim_{n \to \infty} \max_{V \in \mathcal{G}(s, d)} \frac{a_n(\omega, V)}{n}
\]

exists and equals

\[
\inf_{n \in \mathbb{N}} \max_{V \in \mathcal{G}(s, d)} \int_\Omega a_n(\omega, V) \, d\mathbb{P}(\omega).
\]

In particular, one has

\[
\bar{\theta}_s \leq \int_{\Omega} \max_{V \in \mathcal{G}(s, d)} \angle(V, A(\omega)V) \, d\mathbb{P}(\omega).
\]

2. There is a number \(\hat{\theta}_s\) such that for \(\mathbb{P}\)-a.e. \(\omega\),

\[
\hat{\theta}_s = \sup_{V \in \mathcal{G}(s, d)} \limsup_{n \to \infty} \frac{a_n(\omega, V)}{n}.
\]
Furthermore, if for \( \mathbb{P} \)-a.e. \( \omega \) the supremum over \( V \) is achieved by at most \( K < \infty \) subspaces \( V_1(\omega), \ldots, V_K(\omega) \), then one may create \( K \) measurable equivariant collections \( \{V_k(\omega)\}_{1 \leq k \leq K, \omega \in \Omega} \), satisfying \( V_k(T\omega) = A(\omega)V_k(\omega) \), \( k = 1, \ldots, K \).

3. There is a number \( \theta_s \) such that for \( \mathbb{P} \)-a.e. \( \omega \)

\[
\theta_s = \sup_{V \in G(s,d)} \liminf_{n \to \infty} \frac{a_n(\omega,V)}{n}.
\]

Furthermore, if for \( \mathbb{P} \)-a.e. \( \omega \) the supremum over \( V \) is achieved by at most \( K < \infty \) subspaces \( V_1(\omega), \ldots, V_K(\omega) \), then one may create \( K \) measurable equivariant collections \( \{V_k(\omega)\}_{1 \leq k \leq K, \omega \in \Omega} \), satisfying \( V_k(T\omega) = A(\omega)V_k(\omega) \), \( k = 1, \ldots, K \).

4. There is a number \( \bar{\theta}_\infty \) such that

\[
\bar{\theta}_\infty = \lim_{n \to \infty} \sup_{V \in G(s,d)} \esssup_{\omega \in \Omega} \frac{a_n(\omega,V)}{n} = \inf_{n \to \infty} \esssup_{\omega \in \Omega} \sup_{V \in G(s,d)} \frac{a_n(\omega,V)}{n}.
\]

In particular, one has

\[
\bar{\theta}_\infty \leq \esssup_{\omega \in \Omega} \max_{V \in G(s,d)} \varphi(V,A(\omega)V).
\]

5. There is a number \( \bar{\theta}_{\infty}[s] \) such that

\[
\bar{\theta}_{\infty}[s] = \sup_{V \in G(s,d)} \lim_{n \to \infty} \essinf_{\omega \in \Omega} \frac{a_n(\omega,V)}{n} = \sup_{V \in G(s,d)} \essinf_{n \geq 1} \essinf_{\omega \in \Omega} \frac{a_n(\omega,V)}{n}.
\]

In particular, one has

\[
\sup_{V \in G(s,d)} \essinf_{\omega \in \Omega} \varphi(V,A(\omega)V) \leq \bar{\theta}_{\infty}[s].
\]

6. There is a number \( \hat{\theta}_{\infty}[s] \) such that

\[
\hat{\theta}_{\infty}[s] = \sup_{V \in G(s,d)} \lim_{n \to \infty} \esssup_{\omega \in \Omega} \frac{a_n(\omega,V)}{n} = \sup_{V \in G(s,d)} \inf_{n \geq 1} \esssup_{\omega \in \Omega} \frac{a_n(\omega,V)}{n}.
\]

In particular, one has

\[
\hat{\theta}_{\infty}[s] \leq \esssup_{V \in G(s,d)} \esssup_{\omega \in \Omega} \varphi(V,A(\omega)V).
\]

Remark 4.3. In Part 1 of Theorem 4.2, let \( \Omega \) be a metric space, \( \omega \mapsto A(\omega) \) be continuous, and \( T : \Omega \to \Omega \) be uniquely ergodic. Then due to the fact that \( \omega \mapsto \max_V \varphi(V,A(\omega)V) \) is continuous, by Theorem 1.5 [27] we have that the limit in (4.1) converges in the following semi-uniform way (the limit exists for all \( \omega \in \Omega \) and converges uniformly in \( \omega \)): given \( \epsilon > 0 \), there exists \( n_0 \) such that for all \( n \geq n_0 \),

\[
\varphi(\omega,V) \leq \theta_s + \epsilon \quad \text{for all} \quad \omega \in \Omega.
\]

A simple example of such a system is an irrational rotation on the unit circle \( \Omega = S^1 \) and \( T\omega = \omega + \varphi \), where \( \varphi \notin \mathbb{Q} \). Lebesgue measure on \( S^1 \) is the unique invariant probability measure. One may choose any continuous matrix-valued function \( A \). More generally, one may consider rationally independent translations on higher-dimensional tori.
2. By direct computation, one verifies that

\[ V_5 \]

We note that for fixed \( \omega \), as in the proof of Lemma 3.3 one can easily show that

\[
\max_{V \in \mathcal{G}(s,d)} a_{n+m}(\omega, V) \leq \max_{V \in \mathcal{G}(s,d)} a_n(\omega, V) + \max_{V \in \mathcal{G}(s,d)} a_m(T^m\omega, V)
\]

for every \( n, m \geq 0 \), and therefore \( g_n(\omega) := \max_{V \in \mathcal{G}(s,d)} a_n(\omega, V) \) is a subadditive sequence of functions. Recall that \( 0 \leq a_n(\omega, V) \leq \frac{\pi}{2} \) for all \( \omega, V \), implying \( 0 \leq g_n \leq \frac{\pi}{2} \). The results are now immediate by the subadditive ergodic theorem applied to \( g_n \), using ergodicity of \( \mathbb{P} \).

2. By direct computation, one verifies that

\[ a_n(T\omega, A(\omega)V) = a_n(\omega, V) - \angle(V, A(\omega)V) + \angle(A^n(\omega)V, A^{n+1}(\omega)V). \]

Thus, because values of angles are bounded, one has

\[
\limsup_{n \to \infty} \frac{1}{n} a_n(T\omega, A(\omega)V) = \limsup_{n \to \infty} \frac{1}{n} a_n(\omega, V) =: g(\omega, V),
\]

where \( g \) is measurable in \( \omega \) and \( V \). By the invertibility of \( A(\omega) \) for a.e. \( \omega \), we see that

\[ h(\omega) := \sup_{V \in \mathcal{G}(s,d)} g(\omega, V) = \sup_{V \in \mathcal{G}(s,d)} \limsup_{n \to \infty} \frac{1}{n} a_n(T\omega, A(\omega)V) \]

\[ = \sup_{V \in \mathcal{G}(s,d)} \limsup_{n \to \infty} \frac{1}{n} a_n(T\omega, V) = h(T\omega). \]

By ergodicity, the \( T \)-invariant function \( h \) is constant a.e. The expression (4.2) demonstrates equivariance of a particular maximizing \( V \) (if it exists), and due to the invertibility of \( A(\omega) \) \( \mathbb{P} \)-a.e., one can arrange \( K \) maximizing subspaces \( V_1(\omega), \ldots, V_k(\omega) \) (if they exist), which are given pointwise in \( \omega \), into \( K \) measurable families \( \{V_k(\omega)\}_{1 \leq k \leq K, \omega \in \Omega} \).

3. This proof is analogous to Part 2.

4. Since \( V \mapsto \frac{1}{n} a_n(\omega, V) \) is continuous for each \( n \in \mathbb{N} \) and \( \mathbb{P} \)-a.e. \( \omega \), and \( \mathcal{G}(s,d) \) is compact, we may replace the max\( V \in \mathcal{G}(s,d) \) with sup\( V \in \mathcal{G}(s,d) \) in all statements of Part 4. One may now interchange the operations ess sup\( V \) and sup\( V \in \mathcal{G}(s,d) \). Similarly to the proof of Part 1, one shows that sup\( V \in \mathcal{G}(s,d) \) ess sup\( V, a_n(\omega, V) \) is a subadditive sequence. Then the results follow immediately from Fekete’s subadditive lemma.

5. We note that for fixed \( V \) we obtain a superadditive sequence of numbers \( g_n(V) := \text{ess inf}_V a_n(\omega, V) \). By Fekete’s superadditive lemma one has lim\( n \to \infty \) \( g_n(V) \) exists and equals sup\( n \in \mathbb{N} \) \( g_n(V) \). This proves all statements concerning \( \theta_{[s]} \).

6. The results for \( \hat{\theta}_{[s]} \) follow similarly, replacing superadditivity with subadditivity.

Similar to Lemma 3.3 one can show the following relations for the angular values determined by Theorem 4.2:

\[
\theta_{[s]} \leq \theta_{s} \leq \hat{\theta}_{s} \leq \hat{\theta}_{[s]}
\]

\[
\mid \wedge \quad \mid \wedge \quad \mid \wedge \quad \mid \wedge
\]

\[
\theta_{[s]} \leq \theta_{s} \leq \hat{\theta}_{s} \leq \hat{\theta}_{[s]}
\]

Note the equality in the last row due to Part 1 of Theorem 4.2, and the new quantity \( \theta_{[s]} = \liminf_{n \to \infty} \sup_{V \in \mathcal{G}(s,d)} \text{ess inf}_{\omega \in \Omega} \frac{a_n(\omega,V)}{n} \) for which Theorem 4.2 has no information.
In the special case where $\Omega$ consists of a single point, we are in the autonomous setting with a single matrix $A$. We may apply the results of Theorem 4.2 Parts 1–3 to obtain the following corollary.

**Corollary 4.4.** In case $a_n(V) = \sum_{j=0}^{n-1} \angle(A^j V, A^{j+1} V)$ with $A \in \text{GL}(\mathbb{R}^d)$, $V \in \mathcal{G}(s, d)$ the following holds:

1. The limit
   \[
   \overline{\theta}_s := \lim_{n \to \infty} \max_{V \in \mathcal{G}(s, d)} \frac{1}{n} a_n(V) \text{ exists and equals } \inf_{n \in \mathbb{N}} \max_{V \in \mathcal{G}(s, d)} a_n(V).
   \]
   In particular, one has
   \[
   \overline{\theta}_s \leq \max_{V \in \mathcal{G}(s, d)} \angle(V, AV).
   \]

2. There is a number $\hat{\theta}_s$ such that
   \[
   \hat{\theta}_s = \sup_{V \in \mathcal{G}(s, d)} \limsup_{n \to \infty} \frac{1}{n} a_n(V).
   \]
   Furthermore, if the supremum over $V$ is achieved by a subspace $V$ then the supremum is also achieved by $A^j V$ for all $j \in \mathbb{Z}$.

3. There is a number $\underline{\theta}_s$ such that
   \[
   \underline{\theta}_s = \sup_{V \in \mathcal{G}(s, d)} \liminf_{n \to \infty} \frac{1}{n} a_n(V).
   \]
   Furthermore, if the supremum over $V$ is achieved by a subspace $V$ then the supremum is also achieved by $A^j V$ for all $j \in \mathbb{Z}$.

Let us reexamine Example 3.9 where upper and lower inner angular values turned out to be different. In view of Theorem 4.2, this means that the 0, 1 sequence underlying the choice of matrices in Table 3.1 cannot be realized by an ergodic measure preserving map.

**5. Angular values for the autonomous case.** Even in the case of a single matrix $A \in \text{GL}(\mathbb{R}^d)$, Definition 3.1 leads to a nontrivial notion of angular values. Recall from Definition 3.1 that upper values read for $s = 1, \ldots, d$

\[
\overline{\theta}_s(A) = \limsup_{n \to \infty} \frac{1}{n} \sup_{V \in \mathcal{G}(s, d)} \sum_{j=1}^{n} \angle(A^{j-1} V, A^j V),
\]

\[
(5.1) \quad \underline{\theta}_s(A) = \sup_{V \in \mathcal{G}(s, d)} \limsup_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} \angle(A^{j-1} V, A^j V).
\]

Replacing $\limsup_{n \to \infty}$ by $\liminf_{n \to \infty}$ results in the corresponding lower angular values.

The following Proposition provides two equalities in the diagram of (3.5) for autonomous systems.

**Proposition 5.1.** For an invertible autonomous system the following equality holds

\[
\underline{\theta}_s(A) = \overline{\theta}_s(A) = \hat{\theta}_s(A).
\]

20
Proof. The first equality follows from Part 1 of Corollary 4.4, or may be derived directly from Fekete’s lemma. The second equality follows from the definitions via the identity
\[ a_{k+1,k+n}(V) = \sum_{j=k+1}^{k+n} \angle(A^{j-1}V, A^jV) = \sum_{\nu=1}^{n} \angle(A^{\nu-1}A^\nu V, A^\nu V) = a_{1,n}(A^kV). \]

In the following we determine some explicit formulas for angular values in the autonomous case. Proposition 3.7(i) shows that we can assume \( A \) to be in real Schur form (cf. [15, Theorem 2.3.4]), i.e. \( A \) is quasi-upper triangular

\[
A = \begin{pmatrix}
\Lambda_1 & A_{12} & \cdots & A_{1k} \\
0 & \Lambda_2 & \cdots & A_{2k} \\
\vdots & \ddots & \ddots & \vdots \\
0 & \cdots & 0 & \Lambda_k
\end{pmatrix}, \quad \Lambda_i \in \mathbb{R}^{d_i,d_i}, A_{ij} \in \mathbb{R}^{d_i,d_j},
\]

where either \( d_i = 1 \) and \( \Lambda_i = \lambda_i \in \mathbb{R} \) is a real eigenvalue or \( d_i = 2 \) and

\[
\Lambda_i = \begin{pmatrix}
\text{Re}(\lambda_i) & \frac{1}{\rho_i} \text{Im}(\lambda_i) \\
\rho_i \text{Im}(\lambda_i) & \text{Re}(\lambda_i)
\end{pmatrix}, \quad 0 < \rho_i \leq 1,
\]

for a complex eigenvalue \( \lambda_i \in \mathbb{C} \setminus \mathbb{R} \).

5.1. The two-dimensional case. Later on we use (5.2) to reduce the computation of angular values to those of diagonal blocks. Therefore, we look at \( 2 \times 2 \)-matrices first and compute \( \bar{\theta}_1(A) \) in terms of the spectrum \( \sigma(A) \). This is already a nontrivial task. Consider \( A \in \mathbb{R}^{2,2} \) with complex conjugate eigenvalues \( \lambda, \bar{\lambda}, \text{Im}(\lambda) > 0 \) and set \( \varphi = \arg(\lambda) \) where \( \lambda = |\lambda| \exp(i\varphi), 0 < \varphi < \pi \). By orthogonal similarity transformations and a scaling with \( |\lambda|^{-1} \) one can put \( A \) into the normal form (see (5.3))

\[
A(\rho, \varphi) = \begin{pmatrix}
\cos(\varphi) & -\rho^{-1} \sin(\varphi) \\
\rho \sin(\varphi) & \cos(\varphi)
\end{pmatrix}, \quad 0 < \rho \leq 1, \quad 0 < \varphi < \pi.
\]

According to Proposition 3.7(i) these are the transformations which leave all angular values invariant. Further, the matrix \( A(\rho, \varphi) \) leaves the ellipse \( x^2 + \rho^{-2}y^2 = 1 \) invariant, so that \( \rho \leq 1 \) can be achieved by a permutation.

Finally, we introduce the skewness of a matrix \( A \in \text{GL}(\mathbb{R}^d) \) by

\[
\text{skew}(A) = \frac{1}{2r(A)\|A - A^\top\|}, \quad r(A) = \max\{|\lambda| : \lambda \in \sigma(A)\}
\]

and note that this quantity is also invariant under scalings and orthogonal similarity transformations. For the matrix (5.4) we have \( \text{skew}(A(\rho, \varphi)) = \frac{1}{2}(\rho + \rho^{-1})|\sin(\varphi)| \).

Proposition 5.2. For a matrix \( A \in \text{GL}(\mathbb{R}^d) \) all first angular values \( \theta_1(A) \) with \( \theta_1 \in \{\hat{\theta}_1, \hat{\theta}_1, \bar{\theta}_1, \bar{\theta}_1, \hat{\theta}_1, \bar{\theta}_1, \bar{\theta}_1, \hat{\theta}_1\} \) coincide. Moreover, the following holds:
(a) If \( A \) has only real eigenvalues then

\[
\theta_1(A) = \begin{cases}
\frac{\pi}{2}, & \text{if } \sigma(A) = \{-\lambda, \lambda\} \subset \mathbb{R}, \lambda > 0, \\
0, & \text{otherwise}.
\end{cases}
\]
(b) If $\sigma(A) = \{ \lambda, \bar{\lambda} \}, \text{Im}(\lambda) \neq 0$ then

\begin{equation}
\theta_1(A) \leq \min(|\arg(\lambda)|, \pi - |\arg(\lambda)|).
\end{equation}

If additionally, $\text{skew}(A) \leq 1$ then we have equality, i.e.

\begin{equation}
\theta_1(A) = \min(|\arg(\lambda)|, \pi - |\arg(\lambda)|).
\end{equation}

**Proof.** By Proposition 3.7(i) we can assume $A$ to be in Schur form and scale $A$ such that the largest eigenvalue has (absolute) value 1. Further we mention that $\theta_1(A) = 0$ causes all other angular values to vanish by Proposition 5.1 and Lemma 3.3.

For $A = I$ the result is trivial and we are left with the cases

\begin{equation}
A = \begin{cases}
\begin{pmatrix} 1 & \eta \\ 0 & \lambda \end{pmatrix}, & 0 < |\lambda| < 1, \lambda \in \mathbb{R}, \eta \geq 0, \text{ case (i)} \\
\lambda = 1, \eta > 0, & \text{case (ii)} \\
\lambda = -1, \eta \geq 0, & \text{case (iii)} \\
A(\rho, \varphi), & 0 < \rho \leq 1, 0 < \varphi < \pi, \text{ case (iv)}.
\end{cases}
\end{equation}

It suffices to consider spaces $V = \text{span}(v_0)$ where $v_0 = \begin{pmatrix} \cos(\theta_0) \\ \sin(\theta_0) \end{pmatrix}$ and $|\theta_0| \leq \frac{\pi}{2}$. We write the iterates in polar coordinates

\begin{equation}
v_j = A^j v_0, \quad v_j = r_j \begin{pmatrix} \cos(\theta_j) \\ \sin(\theta_j) \end{pmatrix},
\end{equation}

where $r_j = \|v_j\|$ and the angles $\theta_j \in \mathbb{R}$ will be determined appropriately. If $|\theta_j - \theta_{j-1}| \leq \pi$ one finds that the angle between successive spaces is

\begin{equation}\label{angle-formula}
\angle(\text{span}(v_{j-1}), \text{span}(v_j)) = \chi(\theta_j - \theta_{j-1}), \quad \chi(x) := \min(|x|, \pi - |x|).
\end{equation}

In the following we study the matrices from (5.7) case by case.

(i) Since $|\lambda| < 1$ the Blocking Lemma 5.5 below applies and reduces the formula to the one-dimensional case, i.e. $\bar{\theta}_1(A) = \max(\bar{\theta}_1(1), \bar{\theta}_1(\lambda)) = 0$ and similarly for $\bar{\theta}_1, \bar{\theta}_2, \bar{\theta}_3$. Nevertheless, for later use and for the purpose of illustration we discuss the simple subcase $\eta = 0 < \lambda$ explicitly. In this case we obtain $|\theta_j| \leq \frac{\pi}{2}$ for all $j \in \mathbb{N}$ and the following formula

\begin{equation}
\theta_j = \Psi_\lambda(\theta_{j-1}), \quad \Psi_\lambda(\theta) = \begin{cases}
\arctan(\lambda \tan(\theta)), & |\theta| < \frac{\pi}{2}, \\
\theta, & |\theta| = \frac{\pi}{2},
\end{cases}
\end{equation}

cf. Figure 5.1. For $\lambda > 0$ we have $\Psi_\lambda(\theta) > 0$ for all $|\theta| \leq \frac{\pi}{2}$, $0 < \Psi_\lambda(\theta) < \theta$ for $\theta \in (0, \frac{\pi}{2})$, and $0 > \Psi_\lambda(\theta) > \theta$ for $\theta \in (-\frac{\pi}{2}, 0)$. The values $\theta_j$ are monotone decreasing resp. increasing if $\theta_0 > 0$ resp. $\theta_0 < 0$, and therefore

\begin{equation}
a_{1,n} = \sum_{j=1}^{n} \angle(\text{span}(v_{j-1}), \text{span}(v_j)) = \sum_{j=1}^{n} (\theta_{j-1} - \theta_j) = |\theta_0 - \theta_n| \leq \frac{\pi}{2}.
\end{equation}

The assertion then follows from Proposition 3.6 (a) with $\varphi = 0$.  

\pagebreak
(ii) For the matrix in (5.7) (ii) we obtain

\[
\begin{align*}
\theta_j &= \Gamma_\eta(\theta_{j-1}), \\
\Gamma_\eta(\theta) &= \begin{cases} 
\arccot(\eta + \cot(\theta)), & 0 < \theta < \pi, \\
\arccot(-1(\eta + \cot(\theta))), & -\pi < \theta < 0, \\
\theta, & \theta = -\pi, 0, \pi,
\end{cases}
\end{align*}
\]

where arccot_{-1} is the first negative branch of arccot, see Figure 5.1. The function \( \Gamma_\eta \) is strictly monotone increasing and satisfies \( \Gamma_\eta(\theta) < \theta \) for \( 0 < |\theta| < \pi \). Therefore, the sequence \( \theta_j \) is monotone decreasing and converges to 0 if \( 0 \leq \theta_0 < \pi \) and to \(-\pi\) if \( \theta_0 < 0 \). Thus the minimum in (5.9) is achieved at \( |\theta_j - \theta_{j-1}| \) and we obtain as in (5.11)

\[
a_{1,n} = \sum_{j=1}^{n} \angle(\text{span}(v_{j-1}), \text{span}(v_j)) \leq \left| \sum_{j=1}^{n} (\theta_{j-1} - \theta_j) \right| = |\theta_0 - \theta_n| \leq \pi.
\]

(iii) The third case describes a reflection which satisfies \( A^2 = I \). Moreover, we find

\[
v_0^\top A v_0 = \cos(2\theta_0) - \eta \sin(2\theta_0)
\]

which vanishes for \( \theta_0 = \frac{\pi}{4} \) if \( \eta = 0 \), and otherwise for

\[
\theta_0 = \frac{1}{2} \arctan(\eta^{-1}) \in (0, \frac{\pi}{4}).
\]

Then we have \( \angle(v_0, A v_0) = \frac{\pi}{2} = \angle(A^j v_0, A^{j-1} v_0) \) for all \( j \geq 1 \). Since \( \frac{\pi}{2} \) is the maximum possible angular value our assertion is proved. A reflection turns out to have the same angular value as a rotation by \( \frac{\pi}{2} \).

(iv) In (5.7) we can assume \( \varphi \leq \frac{\pi}{2} \) since \( A(\rho, \varphi) \) is orthogonally similar to \( -A(\rho, \pi - \varphi) \). For this rotational case we use ergodic theory and employ almost periodicity; see [21, Ch.4.1, Remarks 1.3-1.7]. We extend the function \( \Psi_\rho \) defined in (5.10) from \([-\frac{\pi}{2}, \frac{\pi}{2}]\) to \( \mathbb{R} \) by setting

\[
(5.13) \quad \Psi_\rho(\theta + n\pi) = \Psi_\rho(\theta) + n\pi, \quad |\theta| \leq \frac{\pi}{2}, \quad n \in \mathbb{Z} \setminus \{0\}.
\]
The new variables

\[
\begin{pmatrix}
\cos(\varphi) & -\rho^{-1}\sin(\varphi) \\
\rho\sin(\varphi) & \cos(\varphi)
\end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & \rho \end{pmatrix} \begin{pmatrix}
\cos(\varphi) & -\sin(\varphi) \\
\sin(\varphi) & \cos(\varphi)
\end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & \rho^{-1} \end{pmatrix}
\]

shows that the angles \( \theta_j \in \mathbb{R} \) in (5.8) are accumulated according to

\[
(5.15) \quad \theta_j = F_{\rho,\varphi}(\theta_{j-1}), j \in \mathbb{N}, \quad F_{\rho,\varphi}(\theta) := \Psi_\rho(\varphi + \Psi_{\rho^{-1}}(\theta)).
\]

The factorization

\[
\begin{pmatrix}
\cos(\varphi) & -\rho^{-1}\sin(\varphi) \\
\rho\sin(\varphi) & \cos(\varphi)
\end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & \rho \end{pmatrix} \begin{pmatrix}
\cos(\varphi) & -\sin(\varphi) \\
\sin(\varphi) & \cos(\varphi)
\end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & \rho^{-1} \end{pmatrix}
\]

may be written by means of a circle map \( T \) with

\[
(5.16) \quad \theta_j = \Psi_\rho(j\varphi + \Psi_{\rho^{-1}}(\theta_0)).
\]

In particular, the values \( \theta_j \) are monotone increasing. From (5.16) and (5.14) we infer

\[
\frac{1}{n}a_{1,n} = \frac{1}{n} \sum_{j=1}^{n} \chi(\theta_{j-1} - \theta_j) \leq \frac{1}{n} \sum_{j=1}^{n} (\theta_j - \theta_{j-1}) = \frac{1}{n} (\theta_n - \theta_0)
\]

\[
= \varphi + \frac{1}{n}(\Psi_\rho(\varphi_n - \varphi) - (\varphi_n - \varphi) + \Psi_{\rho^{-1}}(\theta_0) - \theta_0)
\]

\[
\leq \varphi + \frac{C_\rho + C_{\rho^{-1}}}{n}.
\]

This will lead to the estimate (5.5) as \( n \to \infty \) provided we have shown the equality of all angular values. For this purpose we apply Proposition 3.6(b) where we identify \( V \in \mathcal{G}(1,2) \) with \( \theta + 2\pi \mathbb{Z} \subset S^{2\pi} = \mathbb{R}/(2\pi \mathbb{Z}) \) via \( V = \text{span} \left( \begin{pmatrix} \cos(\theta) \\ \sin(\theta) \end{pmatrix} \right) \). The function \( \Psi_\rho \) is a lift of the circle map \( \psi_\rho : S^{2\pi} \to S^{2\pi} \) defined by \( \psi_\rho(\theta + 2\pi \mathbb{Z}) = \Psi_\rho(\theta) + 2\pi \mathbb{Z} \). Further, the iteration (5.15) may be written by means of a circle map \( T_{\rho,\varphi} : S^{2\pi} \to S^{2\pi} \) as follows

\[
(5.18) \quad \theta_j + 2\pi \mathbb{Z} = T_{\rho,\varphi}(\theta_{j-1} + 2\pi \mathbb{Z}), \quad T_{\rho,\varphi} = \psi_\rho \circ \tau_\varphi \circ \psi_{\rho^{-1}},
\]

where the shift \( \tau_\varphi : S^{2\pi} \to S^{2\pi} \) is defined by \( \tau_\varphi(\theta + 2\pi \mathbb{Z}) = \theta + \varphi + 2\pi \mathbb{Z} \). The map \( F_{\rho,\varphi} \) in (5.15) is then a lift of \( T_{\rho,\varphi} \). It is well known (see [4, Example 2.5]) that \( \tau_\varphi \) is an ergodic isometry of \( S^{2\pi} \) with respect to Lebesgue measure \( \mu_1 \) and the standard metric

\[
d_1(\theta_1 + 2\pi \mathbb{Z}, \theta_2 + 2\pi \mathbb{Z}) = \min_{z \in \mathbb{Z}} |\theta_1 - \theta_2 + 2\pi z|
\]

if and only if \( \frac{\varphi}{\pi} \notin \mathbb{Q} \). In this case the conjugacy (5.18) implies that \( T_{\rho,\varphi} \) is an ergodic isometry of \( S^{2\pi} \) with respect to the image measure \( \mu_\rho = \mu_1 \circ \psi_{\rho^{-1}} \) and the image metric \( d_\rho(\cdot, \cdot) = d_1(\psi_{\rho^{-1}}(\cdot), \psi_{\rho^{-1}}(\cdot)) \). We conclude from [21, Remark 1.3] that the map \( T_{\rho,\varphi} \) is uniformly almost periodic, i.e. for every \( \varepsilon > 0 \) there exists a relatively dense set \( \mathcal{P} \subset \mathbb{N}_0 \) such that \( d_\rho(x, T_{\rho,\varphi}^p x) \leq \varepsilon \) for all \( x \in S^{2\pi}, p \in \mathcal{P} \). Moreover, for any continuous function \( g : S^{2\pi} \to \mathbb{R} \)
the sequence of functions \( b_n(x) = g(T_0^n x), x \in S^{2\pi}, n \in \mathbb{N} \) is uniformly almost periodic in the sense of Definition 3.4. To see this, let \( \varepsilon_0 > 0 \) be given and take \( \varepsilon > 0 \) such that
\[
|g(x_1) - g(x_2)| \leq \varepsilon_0 \quad \text{whenever} \quad d_p(x_1, x_2) \leq \varepsilon, \ x_1, x_2 \in S^{2\pi}.
\]
For the relatively dense set \( P \subset \mathbb{N} \) belonging to \( \varepsilon \) we then find
\[
|b_n(x) - b_{n+p}(x)| = |g(T_0^n x) - g(T_0^p(T_0^n x))| \leq \varepsilon_0, \quad \forall n \in \mathbb{N}, p \in P, x \in S^{2\pi}.
\]
In case \( \frac{\pi}{n} \in \mathbb{Q} \) we have the same result since then every point \( x \in S^{2\pi} \) has the same period \( q \) where \( \frac{\pi}{n} = \frac{2\pi}{q} \).

Let us apply this to the continuous function
\[
g(x) = \min(d_1(x, T_0 x), d_1(x, T_0 x)), \quad x \in S^{2\pi}.
\]
Setting \( x = \theta_0 + 2\pi Z \) we obtain
\[
T_0^{j-1} x = \theta_{j-1} + 2\pi Z, \quad j \in \mathbb{N}.
\]
Using \( \theta_{j-1} < \theta_j \leq \theta_{j-1} + \pi \) and (5.9) for \( j \in \mathbb{N} \) then leads to
\[
b_j(x) = g(T_0^{j-1} x) = \min(\theta_j - \theta_{j-1}, \theta_{j-1} + \pi - \theta_j) = \chi(\theta_j - \theta_{j-1}) = \chi(\text{span}(v_{j-1}), \text{span}(v_j)).
\]
Therefore, all angular values agree by Proposition 3.6 (b).

Next we show that the assumption \( \text{skew}(A) = \frac{1}{2}(\rho + \rho^{-1})|\sin(\varphi)| \leq 1 \) implies \( \theta_j - \theta_{j-1} \leq \frac{\pi}{2} \).

Then the minimum in (5.9) is always achieved with the first term and the first inequality in (5.17) becomes an equality. Thus we find
\[
|\frac{1}{n} a_{1,n} - \varphi| \leq \frac{C_\rho + C_{\rho^{-1}}}{n},
\]
and Proposition 3.6(a) implies the assertion. It remains to analyze the inequality
\[
F_{\rho,\varphi}(\theta) = \Psi_{\rho}(\varphi + \Psi_{\rho^{-1}}(\theta)) \leq \theta + \frac{\pi}{2}, \quad \theta \in \mathbb{R}.
\]

For later purposes we perform a rather explicit calculation. First note that it is enough to consider \( 0 < |\theta| < \frac{\pi}{2} \) since \( F_{\rho,\varphi}(\theta + n\pi) = F_{\rho,\varphi}(\theta) + n\pi \) holds by (5.13) and since (5.21) is obvious for \( \theta = 0, \pm \frac{\pi}{2} \). By the monotonicity of \( \Psi_{\rho^{-1}} \) and the sum formula\(^1\) for arctan we obtain that \( F_{\rho,\varphi}(\theta) \leq \theta + \frac{\pi}{2} \) holds for \( 0 < |\theta| < \frac{\pi}{2} \) if and only if
\[
\varphi \leq \Psi_{\rho^{-1}}(\theta + \frac{\pi}{2}) - \Psi_{\rho^{-1}}(\theta) = \begin{cases} r(\theta, \rho), & 0 < \theta < \frac{\pi}{2}, \\ \pi + r(\theta, \rho), & -\frac{\pi}{2} < \theta < 0, \end{cases}
\]
\[
r(\theta, \rho) := \arctan\left(\frac{\tan(\theta) + \frac{1}{\tan(\theta)}}{\rho^{-1} - \rho}\right) = \arctan\left(\frac{2}{(\rho^{-1} - \rho)\sin(2\theta)}\right).
\]
In case \( \theta > 0 \) this inequality always holds since \( \varphi \leq \frac{\pi}{2} \), while for \( \theta < 0 \) it is equivalent to
\[
\sin(2\theta) \leq \frac{2}{\tan(\varphi)(\rho^{-1} - \rho)} =: \beta(\rho, \varphi).
\]
\(^1\)arctan(x) + arctan(y) = sgn(x)π - arctan(\frac{x + y}{xy - 1}) for \( x \neq 0, xy > 1 \).
Expressing \( \tan(\varphi) \) in terms of \( \sin(\varphi) = \frac{2\text{skew}(A)}{\rho \eta - \rho} \) leads to

\[
\beta(\rho, \varphi) = \left( 1 + \frac{4(1 - \text{skew}(A)^2)}{(\rho^{-1} - \rho)^2} \right)^{1/2}.
\]

Hence condition (5.22) holds for all \( \theta \in \mathbb{R} \) if \( \text{skew}(A) \leq 1 \).

**Remark 5.3.** Let us relate the result of Proposition 5.2 to the theory of rotation numbers; see [17, Ch.11]. First, note that this theory uses \([0, 1]\) instead of \([0, 2\pi]\) as the interval of periodicity. Every matrix \( A \in \text{GL}(\mathbb{R}^2) \) induces a homeomorphism \( f : S^1 \to S^1 \) of \( S^1 = \mathbb{R}/\mathbb{Z} \) via the relation (one step of the iteration (5.8))

\[
(5.24) \quad v = \|v\| \begin{pmatrix} \cos(2\pi x) \\ \sin(2\pi x) \end{pmatrix} \mapsto Av = \|Av\| \begin{pmatrix} \cos(2\pi f(x)) \\ \sin(2\pi f(x)) \end{pmatrix}, \quad x \in S^1.
\]

The homeomorphism is orientation-preserving if and only if \( \det(A) > 0 \). For such a homeomorphism the rotation number \( \tau(f) \in [0, 1] \) is well defined. Iterating (5.24) and comparing with (5.8) then shows the equality \( 2\pi \tau(f) = \theta_1(A) \), provided no vector rotates by more than \( \frac{\pi}{2} \). For the matrices in (5.7) these conditions hold in case (i) if \( \lambda > 0 \), in case (ii), and in case (iv) if \( \text{skew}(A) \leq 1 \) (see (5.15)). The corresponding \( f \)-maps are \( 2\pi f(x) = \Psi_\lambda(2\pi x) \) (see case (i), \( \lambda > 0 \), \( \eta = 0 \), equation (5.10)), \( 2\pi f(x) = \Gamma_\eta(2\pi x) \) (case (ii), equation (5.12)), and \( 2\pi f(x) = \Psi_\rho(\varphi + \Psi_{\rho^{-1}}(2\pi x)) \) (case (iv)). Determining the exact first angular value \( \theta_1(A) \) in case \( \text{skew}(A) > 1 \) of (a) is more involved. In Theorem 6.1 we will show that the inequality (5.5) is generally strict except for some resonant values of \( \varphi = \arg(\lambda) \).

### 5.2. Systems of higher dimension.

As a first step we consider a matrix with a single eigenvalue which generalizes the second case in (5.7).

**Proposition 5.4.** Assume that the spectrum of \( A \in \mathbb{R}^{d,d} \) consists of one eigenvalue \( \lambda \in \mathbb{R}, \lambda \neq 0 \). Then all first angular values vanish, i.e.

\[
\theta_1(A) = 0 \quad \text{for} \quad \theta_1 \in \{ \theta_{[1]}, \theta_{\mid}, \theta_{\mid}, \theta_{\mid}, \theta_{\mid}, \theta_{\mid}, \theta_{\mid}, \theta_{\mid}, \theta_{\mid}, \theta_{\mid} \}.
\]

**Proof.** By Lemma 3.3 and Proposition 5.1 it suffices to show that \( \bar{\theta}_1(A) = 0 \). Further, by Proposition 3.7 we can assume \( \lambda = 1 \) and \( A \) to be in (real) Jordan normal form

\[
(5.25) \quad A = \text{diag}(\Lambda_1, \ldots, \Lambda_k), \quad \Lambda_\ell = I_{d_\ell} + E_\ell \in \mathbb{R}^{d_\ell, d_\ell},
\]

Consider first the case \( k = 1 \) and drop the index \( \ell \). For a vector \( v \in \mathbb{R}^d, v \neq 0 \) let \( d_* = \max\{ j \in \{1, \ldots, d\} : v_j \neq 0 \} \) and assume w.l.o.g. \( v_{d_*+1} = 1 \). Further, we define vectors \( v^j, j \in \mathbb{N}_0 \) and polynomials \( q_i \) of degree \( d_* + 1 - i \) for \( i = 1, \ldots, d_* + 1 \) by

\[
(5.26) \quad v^j := A^j v = \sum_{\nu=0}^{d_*} \binom{j}{\nu} E^\nu v, \quad q_i(j) = (v^j)_i = \sum_{\nu=0}^{d_*+1-i} \binom{j}{\nu} v_{i+\nu}.
\]

If \( d_* = 0 \) then we have \( v^j = v \) for all \( j \in \mathbb{N}_0 \), hence all angles \( \angle(v^j, v^{j+1}) = 0 \) vanish and do not contribute to the supremum in (3.1). Therefore, we can assume \( d_* \geq 1 \). Let
$z_\nu \in \mathbb{C}$, $\nu = 1, \ldots, d_*$ denote the roots of $q_1$ (repeated according to multiplicity) and set $x_\nu = \text{Re}(z_\nu)$. Our goal is to show that there exists a constant $C_* > 0$ independent of $v$ such that for all $j \in \mathbb{N}_0$

\begin{equation}
(5.27) \quad \angle(v^j, v^{j+1}) \leq \frac{C_*}{\min_{\nu=1, \ldots, d_*} |j - x_\nu|}, \quad \text{if } \min_{\nu=1, \ldots, d_*} |j - x_\nu| \geq 1.
\end{equation}

Suppose this has been shown, then the set $M = \bigcup_{\nu=1, \ldots, d_*} (x_\nu - 1, x_\nu + 1)$ contains at most $2d_*$ natural numbers and (5.27) leads to the estimate

\[ \frac{1}{n} \sum_{j=0}^{n-1} \angle(v^j, v^{j+1}) \leq \frac{d_* \pi}{n} + \frac{1}{n} \sum_{j \in \{0, \ldots, n-1\} \setminus M} \sum_{\nu=1, \ldots, d_*} \frac{C_*}{|j - x_\nu|} \leq \frac{d\pi}{n} + \frac{C_*}{n} \sum_{j \in \{0, \ldots, n-1\} \setminus M} \sum_{\nu=1}^{d_*} \frac{1}{|j - x_\nu|} \leq \frac{d\pi}{n} + \frac{C_*}{n} 2d(\log(n) + 1). \]

In the last step we used the standard estimate of the harmonic sum. The right-hand side is independent of $v$, taking the supremum over $v$ and letting $n \to \infty$ shows $\bar{\theta}_1(A) = 0$.

For the proof of (5.27) let us first notice the relation $v^{j+1} - v^j = (A - I_d)v^j = Ev^j$. By (5.26) this leads to the recursion (setting $q_{d_*+2} \equiv 0$)

\begin{equation}
(5.28) \quad q_i(j+1) - q_i(j) = q_{i+1}(j), \quad j \in \mathbb{N}_0, \ i = 1, \ldots, d_* + 1
\end{equation}

and to the expression

\begin{equation}
(5.29) \quad ||v^{j+1} - v^j||^2 = \sum_{i=1}^{d_*+1} q_{i+1}(j)^2 = ||v^j||^2 - q_1(j)^2 \leq ||v^j||^2.
\end{equation}

If $q_1(j) \neq 0$ then Lemma (2.6) (i) applies and yields

\begin{equation}
(5.30) \quad \angle(v^j, v^{j+1}) \leq \tan \angle(v^j, v^{j+1}) \leq \left[ \frac{||v^j||^2 - q_1(j)^2}{q_1(j)^2} \right]^{1/2} \leq \sqrt{\frac{d_*}{\max_{i=2, \ldots, d_*+1} \frac{|q_i(j)|}{|q_1(j)|}}. \right)
\end{equation}

In view of the recursion (5.28) and (5.30) it is sufficient to prove for some constant $C_2$, independent of $v$, and for all $\tau = 0, \ldots, d_*$ the estimate

\begin{equation}
(5.31) \quad \left| \frac{q_2(j+\tau)}{q_1(j)} \right| \leq \frac{C_2}{\min_{\nu=1, \ldots, d_*} |j - x_\nu|}, \quad \text{if } \min_{\nu=1, \ldots, d_*} |j - x_\nu| \geq 1.
\end{equation}
From \( q_1(j) = \prod_{\nu=1}^{d_x}(j - z_\nu) \) and (5.28) we obtain by expanding products
\[
\left| \frac{q_1(j + \tau)}{q_1(j)} \right| = \prod_{\nu=1}^{d_x} |j - z_\nu|^{-1} \prod_{\nu=1}^{d_x} (j - z_\nu + \tau + 1) - \prod_{\nu=1}^{d_x} (j - z_\nu + \tau) \\
= \prod_{\nu=1}^{d_x} |j - z_\nu|^{-1} \sum_{J \subset \{1, \ldots, d_x\}, |J| < d_x} \prod_{\nu \in J} (j - z_\nu) [(\tau + 1)^{d_x - |J|} - \tau^{d_x - |J|}] \\
\leq \sum_{J \subset \{1, \ldots, d_x\}, |J| \geq 1} [(\tau + 1)^{|J|} - \tau^{|J|}] \prod_{\nu \in J} |j - z_\nu|^{-1}.
\]
Because of \( |j - z_\nu| \geq |j - x_\nu| \) and \( |J| \geq 1 \) we have
\[
\prod_{\nu \in J} |j - z_\nu|^{-1} \leq \frac{1}{\min_{\nu=1, \ldots, d_x} |j - x_\nu|}, \quad \text{if} \quad \min_{\nu=1, \ldots, d_x} |j - x_\nu| \geq 1,
\]
which proves (5.31).

The proof is easily adapted to the general Jordan form (5.25). Assertion (5.27) remains the same, but now we have block vectors \( v^j = (v^j_1, \ldots, v^j_k)^T \) and polynomials \( q_{i,\ell,\nu} = 1, \ldots, d_\ell, \ell = 1, \ldots, k \). The formula (5.29) turns into
\[
\|v^{j+1} - v^j\|^2 = \|v^j\|^2 - \sum_{\ell=1}^k q_{1,\ell}(j)^2 = \sum_{\ell=1}^k (\|v^j_{\ell}\|^2 - q_{1,\ell}(j)^2),
\]
and the estimate (5.30) is modified by using
\[
\frac{\|v^j\|^2 - \sum_{\ell=1}^k q^2_{1,\ell}(j)}{\sum_{\ell=1}^k q^2_{1,\ell}(j)} \leq \sum_{\ell=1}^k \frac{\|v^j_{\ell}\|^2 - q_{1,\ell}(j)^2}{q_{1,\ell}(j)^2}.
\]
The subsequent arguments remain unchanged.

To proceed further, we require the following lemma.

**Lemma 5.5.** (Blocking lemma) Let \( \mathbb{R}^d = X_s \oplus X_u \) be a decomposition into invariant subspaces of \( A \in \mathbb{R}^{d,d} \) such that \( A_s = A_1X_s \) and \( A_u = A_1X_u \) satisfy
\[
|\sigma(A_s)| < |\sigma(A_u)|.
\]
Then the following holds for all types of angular values \( \theta_1 \in \{\tilde{\theta}_1, \theta_1, \tilde{\theta}_1, \theta_1\} \)
\[
\theta_1(A) = \max(\theta_1(A_s), \theta_1(A_u)).
\]

**Remark 5.6.** By Proposition 5.1 it is clear that formula (5.33) also holds for the uniform first angular value \( \tilde{\theta}_1(A) \). We did not succeed in proving this for the remaining three uniform first angular values. However, we will be able to treat these three values in the subsequent main Theorem 5.7 under a special assumption.

**Proof.** By scaling \( A \) and (5.32) we can arrange that \( |\sigma(A_s)|, |\sigma(A_u^{-1})| < q < 1 \). Then there exists a constant \( C_\star \) such that
\[
\|A_u^{-1}v_u\| \leq C_\star q\|v_u\|, \quad \|A_sq^jv_s\| \leq C_\star q\|v_s\|, \quad \forall \ v_u \in X_u, v_s \in X_s.
\]
Let us first consider outer angular values and decompose \( v \in \mathbb{R}^d \) as \( v = v_s + v_u, v_s \in X_s, v_u \in X_u \).

The cases \( v_s = 0 \) resp. \( v_u = 0 \) immediately show that \( \theta_1(A) \geq \max(\theta_1(A_s), \theta_1(A_u)) \) holds for \( \theta_1 \in \{ \hat{\theta}_1, \tilde{\theta}_1 \} \). To prove the converse, we assume \( v_u \neq 0 \) and obtain from the triangle inequality

\[
\frac{1}{n} \sum_{j=1}^{n} \angle(A^{j-1}v, A^jv) - \frac{1}{n} \sum_{j=1}^{n} \angle(A^{j-1}v_u, A^jv_u) \leq \frac{2}{n} \sum_{j=1}^{n} \angle(A^jv, A^jv_u).
\]

We show that the right-hand side converges to zero as \( n \to \infty \) for every \( v \). Then the lim inf and the lim sup of the first two sums in (5.35) agree and our assertion follows by taking the supremum over \( v \). With \( C_s, q \) from (5.34) there exist an index \( j_\ast = j_\ast(v) \) such that

\[
2C_s^2q^{2j} \| v_s \| \leq \sqrt{3} \| v_u \|, \quad \text{for all } j \geq j_\ast.
\]

The estimate (2.6) in Lemma 2.6 then shows for \( j \geq j_\ast \)

\[
\angle(A^jv, A^jv_u) \leq \tan \angle(A^jv, A^jv_u) \leq \frac{\| A^jv_u \|}{\left( \| A^jv_u \|^2 - \| A^jv_s \|^2 \right)^{1/2}} \leq \frac{C_sq^j\| v_s \|}{\left( C_s^2q^{-2j}\| v_u \|^2 - C_s^2q^{2j}\| v_s \|^2 \right)^{1/2}} \leq 2C_s^2q^{2j} \| v_s \| \| v_u \|.
\]

Since the right-hand side is summable our conclusion follows.

Next we analyze the inner angular values. By Proposition 5.1 it suffices to consider \( \theta_1 = \hat{\theta}_1 \). As above, Definition 3.1 implies the estimate \( \theta_1(A) \geq \max(\theta_1(A_s), \theta_1(A_u)) \), and it remains to prove the converse. From (5.36) and (5.37) we infer that for each \( v = v_s + v_u \) with \( v_u \neq 0 \) the following index exists

\[
k_\ast = k_\ast(v) = \min\{ j \in \mathbb{N} : \| A^jv_s \| \leq \| A^jv_u \| \}.
\]

Further choose \( j_\ast \) such that \( 2C_s^2q^{2j_\ast} \leq \sqrt{3} \). Then (5.36) holds for \( A^{k_\ast}v_u, A^{k_\ast}v_u \) instead of \( v_s, v_u \) and the estimate (5.37) yields

\[
\angle(A^jv, A^jv_u) \leq 2C_s^2q^{2(j-k_\ast)} \quad \text{for } j - k_\ast \geq j_\ast.
\]

We use \( \| A^{k_\ast-1}v_u \| \leq \| A^{k_\ast-1}v_u \| \), (5.34) and Lemma 2.6 to derive a corresponding estimate of angles to the stable part for \( j \leq k_\ast - j_\ast - 1 \):

\[
\angle(A^jv, A^jv_s) \leq \tan \angle(A^jv, A^jv_s) \leq \frac{\| A^{j-k_\ast+1}(A^{k_\ast-1}v_u) \|}{\left( \| A^{j-k_\ast+1}(A^{k_\ast-1}v_u) \|^2 - \| A^{j-k_\ast+1}(A^{k_\ast-1}v_u) \|^2 \right)^{1/2}} \leq \frac{C_sq^{k_\ast-j-1}\| A^{k_\ast-1}v_u \|}{\left( C_s^2q^{-2(k_\ast-j-1)}\| A^{k_\ast-1}v_s \|^2 - C_s^2q^{2(k_\ast-j-1)}\| A^{k_\ast-1}v_s \|^2 \right)^{1/2}} \leq \frac{C_s^2q^{2(k_\ast-j-1)}\| A^{k_\ast-1}v_u \|}{(1 - C_s^2q^{4(k_\ast-j-1)})^{1/2}\| A^{k_\ast-1}v_s \|} \leq 2C_s^2q^{2(k_\ast-j-1)}.
\]
With these preparations the triangle inequality leads to (recall $\sum_{m}^{n} = 0$ if $m > n$)

$$\frac{1}{n} \sum_{j=1}^{n} \angle(A^{j-1}v, A^{j}v) \leq \frac{1}{n} \left[ \left( \sum_{j=1}^{k_{s}-1-j_{s}} + \sum_{j=k_{s}+1+j_{s}}^{n} \right) \angle(A^{j-1}v, A^{j}v) + (2j_{s} + 1)\frac{\pi}{2} \right]$$

$$\leq \frac{1}{n} \left[ 2C_{s}^{2} \left( \sum_{j=1}^{k_{s}-1-j_{s}} q^{2(k_{s}-j_{s}-1)} + \sum_{j=k_{s}+1+j_{s}}^{n} q^{2(j-s_{j})} \right) + (j_{s} + 1)\pi \right]$$

$$+ \sum_{j=1}^{\min(k_{s},n)} \angle(A^{j-1}v_{s}, A^{j}_{s}v_{s}) + \sum_{j=k_{s}+1}^{n} \angle(A^{j-1}v_{u}, A^{j}_{u}v_{u}) \right].$$

For any given $\varepsilon > 0$, there exists $n_{0} \in \mathbb{N}$ such that for all $k \geq n_{0}$, $v_{s} \in X_{s}$, $v_{s} \neq 0$, $v_{u} \in X_{u}$, $v_{u} \neq 0$ the following holds

$$\sum_{j=1}^{k} \angle(A^{j-1}v_{s}, A^{j}_{s}v_{s}) \leq k(\hat{\theta}_{1}(A_{s}) + \varepsilon), \quad \sum_{j=1}^{k} \angle(A^{j-1}v_{u}, A^{j}_{u}v_{u}) \leq k(\bar{\theta}_{1}(A_{u}) + \varepsilon).$$

Thus we have for $n \geq n_{0}$

$$\sum_{j=1}^{\min(k_{s},n)} \angle(A^{j-1}v_{s}, A^{j}_{s}v_{s}) \leq \begin{cases} \min(k_{s},n)(\hat{\theta}_{1}(A_{s}) + \varepsilon), & k_{s} \geq n_{0}, \\ n_{0}\frac{\pi}{2}, & k_{s} \leq n_{0}. \end{cases}$$

With a similar estimate for $\sum_{j=k_{s}+1}^{n} \angle(A^{j-1}v_{u}, A^{j}_{u}v_{u})$ we obtain for $n \geq n_{0}$ and some constant $C$ independent of $v$ and $n$

$$\frac{1}{n} \sum_{j=1}^{n} \angle(A^{j-1}v, A^{j}v) \leq \frac{1}{n} \left[ C + n_{0}\frac{\pi}{2} + \min(k_{s},n)(\bar{\theta}_{1}(A_{s}) + \varepsilon) \right.$$

$$+ \left. n_{0}\frac{\pi}{2} + (n - \min(k_{s},n))(\hat{\theta}_{1}(A_{u}) + \varepsilon) \right]$$

$$\leq \max(\bar{\theta}_{1}(A_{s}), \hat{\theta}_{1}(A_{u})) + \varepsilon + \frac{1}{n}(C + n_{0}\pi).$$

Now take the supremum over $v \in \mathbb{R}^{d}$, $v_{u} \neq 0$ and then $n$ large so that the last summand is less than $\varepsilon$. This finishes the proof of (5.33).

The following Theorem combines the results of Propositions 5.2, 5.4 and Lemma 5.5.

**Theorem 5.7.** Let the spectrum of $A \in \text{GL}(\mathbb{R}^{d})$ satisfy

$$\lambda \in \sigma(A), \lambda \notin \mathbb{R} \implies \lambda \text{ is simple and } |\eta| \neq |\lambda| \quad \forall \eta \in \sigma(A) \setminus \{\lambda, \bar{\lambda}\}. \tag{5.38}$$

Then all 8 types of angular values $\theta_{1}(A)$ with $\theta_{1} \in \{\hat{\theta}_{1}, \bar{\theta}_{1}, \hat{\theta}_{1}, \bar{\theta}_{1}, \hat{\theta}_{1}, \bar{\theta}_{1}, \hat{\theta}_{1}, \bar{\theta}_{1}\}$ coincide.

Let $\mathbb{R}^{d} = \bigoplus_{i=1}^{k} \mathcal{R}(Q_{i})$, $Q_{i} \in \mathbb{R}^{d_{i},d_{i}}$, $Q_{i}^\top Q_{i} = I_{d_{i}}$ be a decomposition of $\mathbb{R}^{d}$ into invariant subspaces of $A$ corresponding to eigenvalues of equal modulus, i.e.

$$AQ_{i} = Q_{i}A_{i}, \quad A_{i} \in \mathbb{R}^{d_{i},d_{i}}, \quad |\sigma(A_{1})|, \ldots, |\sigma(A_{k})| \text{ pairwise different.} \tag{5.39}$$

Then the following equality holds

$$\theta_{1}(A) = \max_{i=1, \ldots, k} \theta_{1}(A_{i}). \tag{5.40}$$
If there exist two real eigenvalues of opposite sign in $\sigma(A)$ then $\theta_1(A) = \frac{\pi}{2}$. Otherwise, the following estimate holds

$$\theta_1(A) \leq \max_{\lambda \in \sigma(A)} \min(|\arg(\lambda)|, \pi - |\arg(\lambda)|).$$

Equality holds if the maximum on the right-hand side of (5.41) is zero or if it is achieved for an eigenvalue $\lambda_{i_0} \in \sigma(A_{i_0})$, $i_0 \in \{1, \ldots, k\}$ with $\text{Im}(\lambda_{i_0}) \neq 0$ and $\text{skew}(A_{i_0}) \leq 1$; i.e.

$$\theta_1(A) = \min(|\arg(\lambda_{i_0})|, \pi - |\arg(\lambda_{i_0})|).$$

**Remark 5.8.** For the formulas (5.40) and (5.42) it is essential to choose orthonormal bases for the invariant subspaces. Other bases will preserve the spectra of the matrices $A_i$ but neither the values skew($A_i$) nor the angular values $\theta_1(A_i)$, see Proposition 5.2 (b). Except for the first block $\Lambda_1$, the angular values of $\Lambda_1$ in the Schur form (5.2) generally do not agree with $\theta_1(A_i)$, see Algorithm 6.2 and the example in Section 6.3.2.

**Proof.** Let us first prove (5.40) for all 4 nonuniform types of angular value. Note that a decomposition $\mathbb{R}^d = \bigoplus_{i=1}^k \mathcal{R}(Q_i)$ of the desired type always exists since we can decompose $\sigma(A)$ into subsets of equal modulus and then select an orthogonal basis for each of the corresponding invariant subspaces. In this way we transform $A$ into block-diagonal form in a specific way (see (5.39)),

$$A (Q_1 \cdots Q_k) = (Q_1 \cdots Q_k) \text{diag}(A_1, \ldots, A_k).$$

If one does not insist on orthonormal bases for the subspaces then one can keep the diagonal blocks $\Lambda_i$ from the Schur form; see [12, Thm 7.1.6]. From $Q_i^T Q_i = I_d$, we obtain for every $v_i \in \mathbb{R}^{d_i}$, $v_i \neq 0$, $i = 1, \ldots, k$, $j \in \mathbb{N}$,

$$\angle(A_i^{-1}Q_i v_i, A_i^{-1}Q_i v_i) = \angle(Q_i A_i^{-1}v_i, Q_i A_i^{-1}v_i) = \angle(A_i^{-1}v_i, A_i^{-1}v_i),$$

so that all first angular values of $A_i$ and of the restriction $A_i|_{\mathcal{R}(Q_i)}$ coincide. Hence Lemma 5.5 shows (5.40). Note that (5.40) also holds for the $\bar{\theta}[1]$-values by Proposition 5.1.

Now assume that there exist two real eigenvalues $\lambda, -\lambda \in \sigma(A)$ and w.l.o.g. assume $\lambda, -\lambda \in \sigma(A_1)$. Then there exists an orthogonal $S \in \mathbb{R}^{d_1, d_1}$ and some $\eta \in \mathbb{R}$ such that

$$A_1 S = SM, \quad M = \begin{pmatrix} M_{11} & M_{12} \\ 0 & M_{22} \end{pmatrix}, \quad M_{11} = \begin{pmatrix} \lambda & \eta \\ 0 & -\lambda \end{pmatrix}.$$
If such a pair of real eigenvalues does not exist then assumption \((5.38)\) shows that the matrices \(A_i\) are either two-dimensional as in Proposition 5.2 (see case (iv) in (5.7)) or have a single real eigenvalue as in Proposition 5.4. In both cases the propositions guarantee all first angular values of the matrices \(A_i\) to coincide. Thus the four nonuniform angular values of the given matrix \(A\) are equal by \((5.40)\). For \(\theta_{[1]}(A)\) the result then follows from Proposition 5.1. Moreover, Lemma 3.3 yields formula \((5.40)\) and the coincidence of the \(\theta_{[1]}\)-values:

\[
\bar{\theta}_1(B) = \hat{\theta}_1(B) \leq \hat{\theta}_{[1]}(B) \leq \bar{\theta}_{[1]}(B) = \hat{\theta}_1(B), \quad B \in \{A, A_i(i = 1, \ldots, k)\}. 
\]

Next we show \(\theta_{[1]}(A) = \theta_1(A)\). From \((5.40)\) we find an index \(\ell \in \{1, \ldots, k\}\) for which \(\theta_1(A) = \theta_1(A_{\ell})\) holds. Then we use Lemma 3.3 and the equality of angular values from Propositions 5.2 and 5.4,

\[
\theta_1(A) = \theta_{[1]}(A_{\ell}) = \sup_{V_\ell \in \mathcal{G}(1,d_\ell)} \liminf_{n \to \infty} \frac{1}{n} \inf_{k \in \mathbb{N}_0} \sum_{j=k+1}^{k+n} \angle(Q_{\ell}A_{\ell}^{j-1}V_\ell, Q_{\ell}A_{\ell}^jV_\ell) \\
= \sup_{V_\ell \in \mathcal{G}(1,d_\ell)} \liminf_{n \to \infty} \frac{1}{n} \inf_{k \in \mathbb{N}_0} \sum_{j=k+1}^{k+n} \angle(A_{\ell}^{j-1}Q_{\ell}V_\ell, A_{\ell}^jQ_{\ell}V_\ell) \\
\leq \sup_{V \in \mathcal{G}(1,d)} \liminf_{n \to \infty} \frac{1}{n} \inf_{k \in \mathbb{N}_0} \sum_{j=k+1}^{k+n} \angle(A^{j-1}V, A^jV) = \theta_{[1]}(A) \leq \theta_1(A).
\]

Using Lemma 3.3 we obtain the result for the last angular value \(\theta_{[1]}(A)\):

\[
\bar{\theta}_1(B) = \theta_{[1]}(B) \leq \theta_{[1]}(B) \leq \bar{\theta}_1(B) = \theta_1(B), \quad B \in \{A, A_i(i = 1, \ldots, k)\}. 
\]

Finally, the estimate \((5.41)\) follows from \((5.5)\) and Proposition 5.4. If the maximum value on the right of \((5.41)\) is zero then the assertion \((5.42)\) is obvious. Otherwise, it follows from \((5.40)\) and \((5.6)\) in Proposition 5.2 when applied to the \(2 \times 2\) matrix \(A_{i_0}\). ■

Note that condition \((5.38)\) excludes a complex eigenvalue of multiplicity \(\geq 2\) and another eigenvalue of the same modulus. Let us consider such an exceptional case, namely a block diagonal matrix with two rotations

\[
(5.44) \quad A = \begin{pmatrix} T_{\varphi_1} & 0 \\ 0 & T_{\varphi_2} \end{pmatrix}, \quad 0 \leq \varphi_1, \varphi_2 \leq \frac{\pi}{2}.
\]

We claim that every type of angular value is given by

\[
\theta_1(A) = \max(\varphi_1, \varphi_2).
\]

Let \(v = (v_1 \ v_2)^T, \ v_1, v_2 \in \mathbb{R}^2\) and \(|v_1|^2 + |v_2|^2 = 1\). Since \(A\) is orthogonal we obtain

\[
\cos(\angle(Av, v)) = |\langle Av, v \rangle| = |\langle T_{\varphi_1}v_1, v_1 \rangle + \langle T_{\varphi_2}v_1, v_1 \rangle| = |\cos(\varphi_1)|v_1|^2 + |\cos(\varphi_2)|v_2|^2 = |v_1|^2(\cos(\varphi_1) - \cos(\varphi_2)) + |v_2|^2 \cos(\varphi_2).
\]

By the orthogonal invariance of the angle (see Proposition 3.7) this leads to

\[
(5.45) \quad \lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} \angle(A^{j-1}v, A^jv) = \arccos\left(|v_1|^2(\cos(\varphi_1) - \cos(\varphi_2)) + |v_2|^2 \cos(\varphi_2)\right).
\]

32
Suppose w.l.o.g. that $\varphi_2 \geq \varphi_1$ so that $\cos(\varphi_1) - \cos(\varphi_2) \geq 0$. Then the maximum w.r.t. $v$ in (5.45) occurs for $|v_1| = 0$, hence $\theta_1(A) = \varphi_2$. The same argument applies to a block diagonal matrix with $k$ blocks $T_{\varphi_i}$, $i = 1, \ldots, k$ on the diagonal, leading to $\theta_1(A) = \max_{i=1,\ldots,k} \varphi_i$. However, we did not find a formula for $\theta_1(A)$ in cases which violate (5.38) but which are more general than (5.44).

6. Numerical algorithms and results. In this section, our main goal is to discuss algorithms for the computation of the first outer angular value $\hat{\theta}_1(A)$ of an autonomous system generated by a matrix $A \in \mathbb{R}^{d \times d}$, see (5.1). First we investigate the two-dimensional case where our focus is on matrices with $\text{skew}(A) > 1$. We extend the theory underlying Proposition 5.2 and compare with numerical computations.

Then we use the results from Lemma 5.5 and Theorem 5.7 to develop an algorithm for matrices of arbitrary dimension. Let us emphasize that the whole calculation aims at first outer angular values. In the autonomous case we know the coincidence with inner angular values by Theorem 5.7. However, for general nonautonomous systems the computation of inner angular values turns out to be quite involved since one has to solve an optimization problem in every time step.

Let us also note that simple algorithms based on subspace iterations tend to fail. The forward iteration of a generic one-dimensional subspace converges to the most unstable direction. However, we must consider also non-generic directions, i.e. all invariant subspaces, in order to compute $\hat{\theta}_1(A)$. We conclude the section with the computation of the first outer angular value for a nonautonomous linear system obtained by linearizing about a trajectory of the Hénon system. This serves to illustrate the requirements and results of a more general algorithm, see the forthcoming work [6].

6.1. Two dimensional autonomous examples. Consider the two-dimensional models from Proposition 5.2 with increasing skewness. Recall from (5.4) the normal form

$$A(\rho, \varphi) = \begin{pmatrix} \cos(\varphi) & -\rho^{-1} \sin(\varphi) \\ \rho \sin(\varphi) & \cos(\varphi) \end{pmatrix}, \quad 0 < \rho \leq 1, \quad 0 < \varphi \leq \frac{\pi}{2}. \quad (6.1)$$

In the following Table 6.1 we compare for three cases the value of $\varphi$ from its normal form with the numerical value $\hat{\theta}_{1,\text{num}}$ obtained by solving the optimization problem

$$\hat{\theta}_{1,\text{num}} = \max_{v \in \mathbb{R}^2, \|v\|=1} \frac{1}{N} \sum_{j=1}^{N} \angle(A^{j-1}v, A^j v), \quad N = 1000 \quad (6.2)$$

with the MATLAB-routine \texttt{fminbnd}. Note that in this case computations using forward iteration are not spoilt by a dominating direction since $A$ has two eigenvalues of equal modulus.

The first and second example in Table 6.1 have skewness $\leq 1$. Then the numerical angular value $\hat{\theta}_{1,\text{num}}$ agrees with $\min(|\arg(\lambda)|, \pi - |\arg(\lambda)|)$ to machine accuracy, as predicted by Proposition 5.2. However, the third example belongs to the values $\varphi = \arctan(\sqrt{39 \over 5})$, $\rho = \frac{10\sqrt{5} - \sqrt{391}}{\sqrt{39}} \approx {1 \over 7}$ and $\text{skew}(A) \approx 3.37$, so that Proposition 5.2 provides no explicit expression for the first angular value. The solution of (6.2) yields a substantially smaller value $\hat{\theta}_{1,\text{num}} < \varphi$ in this case. Indeed, the first angular value exhibits a rather subtle dependence on the matrix entries for $\text{skew}(A) > 1$. Figure 6.1 (left panel) shows the result

Figure 6.1: Angular value $\hat{\theta}_{1}$ for (6.1) with $\rho = \frac{1}{7}$. Left panel: For 25210 equidistant points $\varphi \in [0, \frac{\pi}{2}]$ the minimal and maximal first angular value are computed by solving an optimization problem; minima and maxima are connected with lines. Right panel: Computation of first angular value via formula (6.3) in Theorem 6.1. Results for case 1 (orange), case 2 (green), case 3 (big points on the diagonal), case 4 (small points above the green curve). In case 4 minima are also shown (small points below the green curve) and connected with corresponding maxima.

Theorem 6.1. For $0 < \rho \leq 1$ and $0 < \varphi \leq \frac{\pi}{2}$ the first angular value $\theta_{1} = \theta_{1}(\rho, \varphi)$ of the
matrix $A = A(\rho, \varphi)$ from (6.1) is given by
\[\theta_1(\rho, \varphi) = \begin{cases} 
\varphi, & \text{skew}(A) \leq 1, \\
\varphi + \frac{1}{\pi} \int_{\delta < 0} \delta(\theta) d\theta, & \text{skew}(A) > 1, \frac{\varphi}{\pi} \notin \mathbb{Q}, \\
\frac{1}{q} \max_{0 \leq \theta \leq \frac{\pi}{2}} \sum_{j=1}^{q} g_j(\theta), & \text{skew}(A) > 1, \frac{\varphi}{\pi} = \frac{p}{q}, q \geq 2,
\end{cases}\]

Here the functions $g_j, \delta : [0, \pi] \to \mathbb{R}, j \in \mathbb{N}$ are defined as follows:
\[\delta(\theta) = 2\Psi_\rho(\theta) - 2\Psi_\rho(\theta + \varphi) + \pi, \quad \text{with } \Psi_\rho \text{ from (5.10)},\]
\[g_j(\theta) = \min(\theta_j - \theta_{j-1}, \theta_{j-1} + \pi - \theta_j), \quad \theta_{j-1} = \Psi_\rho((j-1)\varphi + \Psi_{\rho-1}(\theta)).\]

If $\frac{\pi}{2} < \varphi < \pi$ then $\theta_1(\rho, \varphi) = \theta_1(\rho, \pi - \varphi)$.

**Proof.** By Proposition 5.2 it suffices to consider $\text{skew}(A(\rho, \varphi)) = \frac{1}{2}(\rho + \rho^{-1}) \sin(\varphi) > 1$. In the nonresonant case $\frac{\varphi}{\pi} \notin \mathbb{Q}$ we return to the proof of Proposition 5.2, case (iv). Let us apply Birkhoff’s ergodic theorem to the ergodic isometry $T_{\rho, \varphi}$ of $(S^{2\pi}, d_\rho, \mu_\rho)$ (see (5.18)) and to the continuous map $g$ from (5.19),
\[\theta_1(\rho, \varphi) = \lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} g(T_{\rho, \varphi}^{j-1} \xi) = \frac{1}{2\pi} \int_{S^{2\pi}} g(y) d\mu_\rho(y) = \frac{1}{2\pi} \int_{S^{2\pi}} g(\psi_\rho(x)) d\mu_1(x).\]

The second equality is due to the transformation formula. Also note that the convergence is uniform in $\xi \in S^{2\pi}$, see [21, Ch.4.1, Remark 1.5]. We evaluate the integrand for
We investigate the minimum by looking at the sign of the difference in case skew(A) > 1 implies δ ≥ 0 in [0, π] by (5.22), (5.23), and therefore the angular value \( \theta_1(\rho, \varphi) \) in this case is given by

\[
\theta_1(\rho, \varphi) = \frac{1}{2\pi} \int_0^{2\pi} \min(\Psi_\rho(\theta + \varphi) - \Psi_\rho(\theta), \Psi_\rho(\theta + \pi) - \Psi_\rho(\theta + \varphi)) d\theta
\]

where the last equality follows from \( \Psi_\rho(\theta) \leq \Psi_\rho(\theta + \varphi) < \Psi_\rho(\theta + \pi) = \Psi_\rho(\theta) + \pi \). Combining this with (6.4) and using (5.13) leads to

\[
\theta_1(\rho, \varphi) = \frac{1}{2\pi} \int_0^{2\pi} \min(\Psi_\rho(\theta + \varphi) - \Psi_\rho(\theta), \Psi_\rho(\theta + \pi) - \Psi_\rho(\theta + \varphi)) d\theta
\]

We investigate the minimum by looking at the sign of the difference

\[
\Psi_\rho(\theta + \pi) - \Psi_\rho(\theta + \varphi) - (\Psi_\rho(\theta + \varphi) - \Psi_\rho(\theta)) = \delta(\theta).
\]

Let us note in passing that skew(A) ≤ 1 implies δ ≥ 0 in [0, π] by (5.22), (5.23), and therefore the angular value \( \theta_1(\rho, \varphi) \) in this case is given by

\[
\theta_1(\rho, \varphi) = \frac{1}{2\pi} \int_0^{2\pi} \min(\Psi_\rho(\theta + \varphi) - \Psi_\rho(\theta), \Psi_\rho(\theta + \pi) - \Psi_\rho(\theta + \varphi)) d\theta
\]

where the values \( \theta_\pm \) are given as follows

\[
\theta_\pm = \Psi_\rho^{-1}(\theta_\pm'),
\]

\[
\theta_\pm' = \frac{1}{2} \arcsin \left( \frac{2}{\tan(\varphi)(\rho^{-1}-\rho)} \right) \in (0, \frac{\pi}{4}), \quad \theta_+ = \frac{\pi}{2} - \theta_- \in (\frac{\pi}{4}, \frac{\pi}{2}).
\]

Using the integral from (6.5), this finally proves the second case in (6.3)

\[
\theta_1(\rho, \varphi) = \frac{1}{\pi} \left\{ \int_{\theta_-}^{\theta_+} \Psi_\rho(\theta + \varphi) - \Psi_\rho(\theta) d\theta + \int_{\theta_-}^{\theta_+} \Psi_\rho(\theta + \pi) - \Psi_\rho(\theta + \varphi) d\theta \right\}
\]

\[
= \frac{1}{\pi} \left\{ \int_0^{\pi} \Psi_\rho(\theta + \varphi) - \Psi_\rho(\theta) d\theta + \int_{\theta_-}^{\theta_+} \delta(\theta) d\theta \right\}
\]

\[
= \varphi + \frac{1}{\pi} \int_{\theta_-}^{\theta_+} \delta(\theta) d\theta = \varphi + \frac{1}{\pi} \int_{\{\delta<0\}} \delta(\theta) d\theta.
\]

Next we consider \( \frac{\varphi}{\pi} = \frac{p}{q} \) for some natural numbers 0 < p ≤ q. From the definition (5.18) of \( T_{\rho,\varphi} \) we obtain

\[
T_{\rho,\varphi}^q = \psi_\rho \circ \tau_\varphi^q \circ \psi_\rho^{-1} = \psi_\rho \circ \tau_{p\pi} \circ \psi_\rho^{-1} = \tau_{p\pi}.
\]
where we used $\psi_\rho \circ \tau_\pi = \tau_\pi \circ \psi_\rho$ due to (5.13). Moreover, translation invariance of the metric $d_1$ yields that the function $g$ in (5.19) is $\pi$-periodic:

$$
g(\tau_\pi x) = \min(d_1(\tau_\pi x, T_{\rho,\varphi}(\tau_\pi x)), d_1(\tau_\pi x, T_{\rho,\varphi}(\tau_\pi x)))
= \min(d_1(\tau_\pi x, \tau_\pi(T_{\rho,\varphi} x)), d_1(x, \tau_\pi(T_{\rho,\varphi} x)))
= \min(d_1(x, T_{\rho,\varphi} x), d_1(\tau_\pi x, T_{\rho,\varphi}(\tau_\pi x)))
= \min(d_1(x, T_{\rho,\varphi} x), d_1(\tau_\pi x, T_{\rho,\varphi}(\tau_\pi x))) = g(x).$$

Therefore, decomposing $n = kq + r$ with $k \geq 0$, $1 \leq r \leq q$ leads to

$$
\frac{1}{n} \sum_{j=1}^{n} g(T_{\rho,\varphi}^{j-1} x) = \frac{1}{n} \left( \sum_{\nu=0}^{k-1} \sum_{\ell=1}^{q} g(T_{\rho,\varphi}^{\nu q + \ell - 1} x) + \sum_{\ell=1}^{r} g(T_{\rho,\varphi}^{kq + \ell - 1} x) \right)
= \frac{1}{n} \left( \sum_{\nu=0}^{k-1} \sum_{\ell=1}^{q} g(\tau_{\nu p\pi}(T_{\rho,\varphi}^{\ell - 1} x)) + \sum_{\ell=1}^{r} g(\tau_{kp\pi}(T_{\rho,\varphi}^{\ell - 1} x)) \right)
= \frac{k}{kq + r} \sum_{\ell=1}^{q} g(T_{\rho,\varphi}^{\ell - 1} x) + \frac{1}{n} \sum_{\ell=1}^{r} g(T_{\rho,\varphi}^{\ell - 1} x) \rightarrow \frac{1}{q} \sum_{\ell=1}^{q} g(T_{\rho,\varphi}^{\ell - 1} x).
$$

Maximizing over $x = \theta_0 + 2\pi Z$ and using (5.20) then proves the last formula in (6.3). It remains to show that the maximum in case $p = 1$ is given by $\varphi = \pi q$. In this case we have $T_{\rho,\varphi} = \tau_\pi$ and thus equation (5.20) yields for all $\theta_0 \in [0, \pi]$

$$
\frac{1}{q} \sum_{\ell=1}^{q} g(T_{\rho,\varphi}^{\ell - 1} x) = \frac{1}{q} \sum_{\ell=1}^{q} \chi(\theta_j - \theta_{j-1}) \leq \frac{1}{q} \sum_{j=1}^{q} (\theta_j - \theta_{j-1}) = \frac{1}{q} (\theta_q - \theta_0) = \frac{\pi}{q} = \varphi.
$$

We set $\theta_0 = \theta_-$ and recall that $\theta_-$ has been chosen such that $\theta_1 - \theta_0 = \frac{\pi}{2}$. Since $\theta_j - \theta_{j-1} \geq 0$ sum up to $\pi$ there is no index $j > 1$ with $\theta_j - \theta_{j-1} > \frac{\pi}{2}$, hence equality holds in (6.6). 

\section*{6.2. An algorithm for computing first angular values}

Based on Theorem 6.1 and on the results from Section 5, we propose the following numerical scheme for autonomous systems. In case $A \in \mathbb{R}^{d,d}$ is invertible and satisfies the assumption (5.38) our numerical approach is justified by Theorem 5.7.
Algorithm 6.2 Computation of \( \hat{\theta}_1(A) \)

1. Compute a real Schur decomposition of \( A \)

\[
A = QSQ^T, \quad S = \begin{pmatrix}
\Lambda_1 & \ast \\
\ast & \cdots \\
0 & \Lambda_k
\end{pmatrix}, \quad Q \in \mathbb{R}^{d \times d} \text{ orthogonal, cf. (5.2)},
\]

such that the diagonal blocks \( \Lambda_1, \ldots, \Lambda_\ell \) are two-dimensional and \( \Lambda_{\ell+1}, \ldots, \Lambda_k \) are reals (such a Schur decomposition always exists, see [15, Theorem 2.3.4]). Let \( \lambda_i, \bar{\lambda}_i \) be the eigenvalues of \( \Lambda_i \), \( i = 1, \ldots, \ell \) and let \( A_i = \lambda_i = \bar{\lambda}_i \) for \( i = \ell + 1, \ldots, k \).

2. Compute \( \hat{\theta}_1(A) \) as follows

\[
\text{if } \exists i \neq j \in \{\ell + 1, \ldots, k\} : \lambda_i = -\lambda_j \text{ then}
\]

\[
\hat{\theta}_1(A) = \frac{\pi}{2}
\]

\[
\text{else for } i = 1, \ldots, \ell \text{ do}
\]

\[
\text{if } i = 1 \text{ then } A_1 = \Lambda_1
\]

\[
\text{else Compute a reordered Schur decomposition of } A \text{ using ordschur, such that the upper left } 2 \times 2\text{-block has the eigenvalue } \lambda_i.
\]

\[
\text{Denote this upper left } 2 \times 2\text{-block by } A_i.
\]

\[
\text{end if}
\]

\[
\text{Determine } \varphi_i, \rho_i \text{ such that } A_i = |\lambda_i|A(\rho_i, \varphi_i).
\]

\[
\text{Compute } \hat{\theta}_1(A_i) = \theta_1(A(\rho_i, \varphi_i)) \text{ using Theorem 6.1.}
\]

\[
\text{end for}
\]

\[
\hat{\theta}_1(A) = \max\{0, \hat{\theta}_1(A_i), i = 1, \ldots, \ell\}.
\]

\[
\text{end if}
\]

As explained in Remark 5.8, the Schur decomposition of \( A \) is reordered several times to obtain the diagonal blocks \( A_i, i = 2, \ldots, \ell \). We apply the MATLAB command ordschur for this task.\(^2\) The value \( \theta_1(A(\rho_i, \varphi_i)) \) is calculated for \( i = 1, \ldots, \ell \) with Theorem 6.1. Note that the fourth case in (6.3) results in a one-dimensional optimization problem which we solve with a derivative-free method implemented in the MATLAB-routine fminbnd.

6.3. Numerical experiments. Let us apply Algorithm 6.2 to autonomous models with increasing complexity and dimension. The example in Section 6.3.2 particularly illustrates the need for reordering the Schur decomposition in Algorithm 6.2. Finally, we give an outlook regarding numerical techniques for angular values in nonautonomous systems. We refer to the forthcoming publication [6] for details of the algorithm and its analysis.

6.3.1. Block-diagonal examples. We begin with autonomous examples which have a block-diagonal structure. Due to the invariance of corresponding coordinate spaces, one can read off first angular values without the need for reordering Schur decompositions. Furthermore, the numerical calculation can be done with high accuracy and even exactly when these expressions are evaluated symbolically. Therefore, approximation errors are

\(^2\)We are not aware of a MATLAB procedure that computes the block decomposition (5.43) directly.
not discussed in Table 6.2.

\[
\begin{array}{c|c|c|c|c|c}
A & A_1 & \hat{\theta}_1(A_1) & A_2 & \hat{\theta}_1(A_2) & \hat{\theta}_1(A) \\
\hline
\left( \begin{array}{cc} 2 & 0 \\ 0 & \frac{\pi}{2} \end{array} \right) & 2 & 0 & 3 & 0 & 0 \\
\hline
\left( \begin{array}{cc} 2 & 0 \\ 0 & -2 \end{array} \right) & 2 & 0 & -2 & 0 & \frac{\pi}{2} \\
\hline
\left( \begin{array}{cc} \phi & s \\ s & -c \end{array} \right) & 1 & 0 & -1 & 0 & \frac{\pi}{2} \\
\hline
\left( \begin{array}{cc} c -s & 0 \\ 0 & -2 \end{array} \right) & \varphi & \varphi & -2 & 0 & \varphi \\
\end{array}
\]

Table 6.2: Angular values of block-diagonal examples. We abbreviate \( c = \cos(\varphi), s = \sin(\varphi), 0 < \varphi < \frac{\pi}{2} \).

6.3.2. An illustrative four-dimensional example. Using the normal form (6.1) we consider a \( 4 \times 4 \)-matrix which has already Schur form

\[
A = \left( \begin{array}{cc} A(1, \frac{1}{2}) & I_2 \\ 0 & \eta A(\frac{1}{2}, 1.4) \end{array} \right) = \left( \begin{array}{cc} \Lambda_1 & I_2 \\ 0 & \Lambda_2 \end{array} \right)
\]

with \( \eta = 1.2 \). For this matrix we have \( \theta_1(\Lambda_1) = \frac{1}{2} \) and \( \theta_1(\Lambda_2) = 1.128 \). The algorithm sets \( A_1 = \Lambda_1 \) and reorders the Schur form so that the eigenvalues of \( \Lambda_2 \) appear in the first \( 2 \times 2 \)-block:

\[
Q^T A Q = \left( \begin{array}{cc} \eta A(0.7493, 1.4) & * \\ 0 & A(0.6142, 1.4) \end{array} \right), \quad \text{whereby } A_2 = \eta A(0.7493, 1.4).
\]

From Theorem 6.1 the algorithm then finds \( \theta_1(A_2) = 1.355 \) and thus we have

\[
\max(\theta_1(\Lambda_1), \theta_1(\Lambda_2)) = 1.128 < 1.355 = \max(\theta_1(A_1), \theta_1(A_2)) = \theta_1(A).
\]

This example illustrates that first angular values can generally not be computed from the diagonal blocks of a single Schur decomposition.

6.3.3. High dimensional examples. We illustrate the performance of our algorithm for three matrices of dimension \( 10^3 \), \( 10^4 \) and \( 10^4 \). Their entries are uniformly distributed in \((0, 1)\) and generated by the MATLAB random number generator initialized with \texttt{rng(1)}.

Table 6.3 documents our numerical results. We measure the time for the initial Schur decomposition and the maximal time for one reordering with \texttt{ordschur}. It turns out that the computing time for one reordering step grows linearly with the position \( i \) of the block \( \Lambda_i \) in the Schur form. The numerical experiments are carried out on an Intel Xeon W-2140B CPU with MATLAB 2020A.

Applying Algorithm 6.2 to the \( 10^4 \)-dimensional random matrix yields \( \ell = 4958 \) two-dimensional blocks for which we calculate the first angular value, using Theorem 6.1. Then there are 84 real eigenvalues of different modulus leading to a vanishing angular value. Summing up we obtain \( k = 5042 \) one- resp. two-dimensional blocks \( A_i \). For the presentation in Figure 6.3, these blocks are rearranged, such that

\[
\theta_1(A_i) \leq \theta_1(A_{i+1}) \quad \text{for all } i = 1, \ldots, k - 1.
\]
The left panel shows a plot of the pairs \((i, \theta_1(A_i))\)\(_{i=1,...,k}\). Except for an initial ramp due to the 84 real eigenvalues, the plot suggests an almost uniform distribution of angular values. This is also confirmed by the corresponding histogram shown in the right panel. As expected, further experiments show no correlation between the modulus \(|\lambda_i|\) of the eigenvalue and the angular value \(\theta_1(A_i)\) of the corresponding \(2 \times 2\) matrix \(A_i\).

**6.3.4. An experiment with a nonlinear system.** Let \(F : \mathbb{R}^d \to \mathbb{R}^d\) be a nonlinear mapping with a hyperbolic fixed point \(\xi \in \mathbb{R}^d\). Linearizing the system \(x_{n+1} = F(x_n)\) about the fixed point one obtains the autonomous variational equation

\[
(6.8) \quad u_{n+1} = DF(\xi)u_n, \quad n \in \mathbb{N}_0,
\]

to which Algorithm 6.2 applies and provides an approximation of \(\hat{\theta}_1(DF(\xi))\).

Rather than fixed points, our interest is in a bounded trajectory \((\xi_n)_{n \in \mathbb{N}_0}\),

\[
\xi_{n+1} = F(\xi_n), \quad n \in \mathbb{N}_0 \quad \text{with initial point } \xi_0 \in \mathbb{R}^d
\]

lying, for example, on an attractor. In this setup, the variational equation

\[
(6.9) \quad u_{n+1} = DF(\xi_n)u_n, \quad n \in \mathbb{N}_0
\]

is nonautonomous and Algorithm 6.2 does not apply. The development of an algorithm for angular values in nonautonomous systems and its rigorous justification is quite involved.
and is the topic of the forthcoming paper [6]. Nevertheless, we indicate here the problems of such a generalization and provide a numerical result for a specific example. It is well-known that eigenvalues of the single matrices $DF(\xi_n)$, $n \in \mathbb{N}_0$ are generally irrelevant for describing nonautonomous dynamics, cf. [28]. Instead, exponential dichotomies provide adequate spectral information. Roughly speaking, one replaces the eigenvalue spectrum by the dichotomy (or Sacker-Sell) spectrum and the eigenspaces by corresponding spectral bundles. Then the aim is to show that angular values are achieved in certain directions resp. subspaces within the spectral bundles and to use this fact for setting up an algorithm for the general nonautonomous case. Results of this type and further applications to higher angular values for systems of dimension $d \geq 3$ will be presented in detail in [6].

Here we use for illustration the two-dimensional Hénon map, see [14]

\begin{equation}
F \left( \begin{array}{c}
x_1 \\ x_2
\end{array} \right) = \begin{pmatrix}
1 + x_2 - 1.4x_1^2 \\ 0.3x_1
\end{pmatrix}.
\end{equation}

The map (6.10) possesses the hyperbolic fixed point $\xi \approx \left( 0.63 \ 0.19 \right) \top$ and the Jacobian $DF(\xi)$ has two real eigenvalues $\lambda_1 \approx 0.16$, $\lambda_2 \approx -1.92$. Proposition 5.2 as well as Algorithm 6.2 apply to the linear autonomous system (6.8) and both yield $\theta_1(DF(\xi)) = 0$ for all types $\theta_1$ of angular values. Geometrically, the two eigenspaces are tangent spaces to the stable and unstable manifolds of $\xi$, cf. [26, Chapter 5]. From $\theta_1(DF(\xi)) = 0$ we infer that these one-dimensional tangent spaces do not rotate in time, see Figure 6.4.

![Figure 6.4: Stable (green) and unstable (red) manifold of the fixed point $\xi$ of (6.10). In addition, the corresponding tangent spaces are shown.](image)

Next, we consider the nonautonomous variational equation (6.9) for the trajectory $(\xi_n)_{n \in \mathbb{N}_0}$ with initial point $\xi_0 = \left( -0.4363 \ 0.2873 \right) \top$. This bounded trajectory is close to the Hénon attractor. The algorithm proposed in [6] yields for this model the approximate first outer angular value $\hat{\theta}_1 = 0.7525$. This value results from the stable tangent bundle to the invariant fibers of the bounded trajectory $(\xi_n)_{n \in \mathbb{N}_0}$ which turns out to rotate faster than the unstable tangent bundle. Both tangent spaces are shown in green and red in Figure 6.5. We also refer to Figure 1.1 in the Introduction where the stable tangent spaces are shifted to the origin to visualize their successive rotations.

Appendix A. Auxiliary results.

A.1. Variational characterization of maximum principal angle.

Proof. (Proposition 2.3)
We use the following elementary fact

\[(A.1) \max_{y \in \mathbb{R}^j, \|y\| = 1} v^\top y = \|v\| \quad \forall \ v \in \mathbb{R}^j, v \neq 0,\]

with the maximum achieved at \(y = \frac{1}{\|v\|} v\) for \(v \neq 0\). Consider \(w \in W\) with \(\|w\| = 1\) and \(w^\top w_\ell = 0\), \(\ell = j + 1, \ldots, s\). By Proposition 2.2 there exists \(b \in \mathbb{R}^s\) such that

\[(A.2) \quad w = Qb = QZZ^\top b = (w_1 \cdots w_s) Z^\top b.\]

Since \(\|w\| = 1\) and \(w^\top w_\ell = 0\) for \(\ell = j + 1, \ldots, s\) we obtain the partitioning

\[Z^\top b = \begin{pmatrix} b^I \v 0 \end{pmatrix}, b^I \in \mathbb{R}^j, \|b^I\| = 1, \quad Z = \begin{pmatrix} Z^I Z^{II} \end{pmatrix}, Z^I \in \mathbb{R}^{d,j}.\]

By (A.1) this implies for all \(v \in \mathbb{R}^d, v \neq 0\)

\[(A.3) \quad \max_{w \in W, \|w\| = 1, \quad w^\top w_\ell = 0, \ell = j + 1, \ldots, s} v^\top w = \max_{b^I \in \mathbb{R}^j, \|b^I\| = 1} v^\top QZ^I b^I = \|Z^I Q^\top v\|.
\]

In a similar way, for \(v \in \mathbb{R}^d\) with \(\|v\| = 1\) and \(v^\top v_\ell = 0\) for \(\ell = j + 1, \ldots, d\) we find vectors \(a \in \mathbb{R}^d, a^I \in \mathbb{R}^j\) such that

\[v = Pa = PYY^\top a = (v_1 \cdots v_s) Y^\top a, \quad Y^\top a = \begin{pmatrix} a^I \v 0 \end{pmatrix}, \quad \|a^I\| = 1.\]
Using this and (2.2) in (A.3) and setting $\Sigma = \text{diag}(\sigma_1, \ldots, \sigma_j)$ leads to

$$
\min_{v \in V, \|v\| = 1} \max_{w \in W, \|w\| = 1} v^Tw = \min_{a^I \in \mathbb{R}^j, \|a^I\| = 1} \| Z^TQ^T P Y (a^I) \| = \min_{a^I \in \mathbb{R}^j, \|a^I\| = 1} \| Z^TZ \Sigma (a^I) \|
$$

Since $\sigma_1 \geq \ldots \geq \sigma_j$ the last minimum is $\sigma_j$ and it is achieved at the $j$-th unit vector $a^I = e^I_j \in \mathbb{R}^j$. With Proposition 2.2 this yields the minimizer $v = PYe^I_j = v_j$, where $e^I_j = \left( e^I_j, 0 \right) \in \mathbb{R}^d$. Returning to (A.3) we obtain the maximizer $b^I = \frac{1}{\sigma_j} Z^TQ^Tv_j$ where $\sigma_j = \| Z^TQ^Tv_j \|$ is the maximum value. By (A.2) and (2.3) this leads to the maximizer of the original problem

$$
w = \frac{1}{\sigma_j} QZ \left( Z^TQ^Tv_j \right) = \frac{1}{\sigma_j} QZ \left( Z^TQ^TPYe^I_j \right)
$$

Finally, note that taking arccos reverses min and max in (2.5). 

\section*{A.2. Uniform almost periodicity.}
We use the following result in the proof of Proposition 3.6.

**Lemma A.1.** Let $b_n : \mathcal{V} \to \mathcal{W}$, $n \in \mathbb{N}$ be a sequence of uniformly almost periodic and uniformly bounded functions. Then for all $\varepsilon > 0$ there exists $N \in \mathbb{N}$ such that for all $n \geq m \geq N$, $k \in \mathbb{N}$, $V \in \mathcal{V}$

$$
\left\| \frac{1}{n} \sum_{j=1}^{n} b_j(V) - \frac{1}{m} \sum_{j=1}^{m} b_{j+k}(V) \right\| \leq \varepsilon.
$$

**Proof.** Let $\varepsilon > 0$. By the uniform almost periodicity there exists a $P \in \mathbb{N}$ such that for every $V \in \mathcal{V}$ we find a $p \in \{1, \ldots, P+1\}$ (which may depend on $V$) such that

$$
\|b_n(V) - b_{n+p}(V)\| \leq \frac{\varepsilon}{4} \quad \forall n \in \mathbb{N}.
$$

Let $b_\infty = \sup_{n,V} \|b_n(V)\|$, $N = \lceil \frac{1}{8}(P+1)b_\infty \rceil$ and decompose $n \geq m \geq N$ modulo $p$, i.e.

$$
m = \ell_mp + r_m, \quad 0 \leq r_m < p, \quad n = \ell_n p + r_n, \quad 0 \leq r_n < p.
$$
For $c_p(V) := \sum_{j=1}^p b_j(V)$ we obtain from (A.4) for each $k \in \mathbb{N}_0$ the estimates
\[
\left\| \frac{1}{n} \sum_{j=1}^n b_j(V) - \frac{1}{m} \sum_{j=1}^m b_{j+k}(V) \right\| \\
\leq \left\| \frac{1}{n} \sum_{j=1}^{p\ell_m} b_j(V) - \frac{1}{m} \sum_{j=1}^{p\ell_m} b_{j+k}(V) \right\| + \left\| \frac{1}{n} \sum_{j=p\ell_m+1}^{p\ell_m+r} b_j(V) - \frac{1}{m} \sum_{j=p\ell_m+1}^{p\ell_m+r} b_{j+k}(V) \right\| \\
\leq \left\| \frac{1}{n} \sum_{j=1}^{p\ell_m} b_j(V) - \frac{\ell_n}{n} c_p(V) \right\| + \left\| \frac{\ell_n}{n} c_p(V) - \frac{\ell_m}{m} c_p(V) \right\| \\
+ \left\| \frac{\ell_m}{m} c_p(V) - \frac{1}{m} \sum_{j=1}^{p\ell_m} b_{j+k}(V) \right\| + \left\| \frac{1}{n} \sum_{j=p\ell_m+1}^{p\ell_m+r} b_j(V) - \frac{1}{m} \sum_{j=p\ell_m+1}^{p\ell_m+r} b_{j+k}(V) \right\| \\
\leq \frac{\ell_n p \varepsilon}{n} + \frac{\varepsilon}{4} + \frac{\ell_m p \varepsilon}{m} + \frac{2(P + 1)}{N} b_\infty \leq \varepsilon.
\]
